Homogeneous sample pulp, prepd. from fruits and vegetables of different water content with or without addnl. water, was adsorbed on the surface of activated Florisil to obtain a free-flowing powder, which was extd. in a glass column with EtOAc or CH2Cl2-Me2CO (9:1). In most cases, no further cleanup was necessary for subsequent gas chromatog. The recovery of pesticide residues, including carbamate, organochlorine, organophosphate, synthetic pyrethroid, triazine, urea, and misc. pesticides, was generally >=80%, and was independent of the sample material. The column extn. was faster, less laborious, and less expensive than extns. based on traditional techniques, liq. partition, or other conventional chromatog. procedures. 628. Kagan Y, S., Voronina, V. M., and Akkerman, G. (Effect of Phthalophos on the Embryogenesis and Its Metabolism in Albino Rats and Their Embryos. *Gig Sanit.*
Chem Codes: Chemical of Concern: PSM Rejection Code: NON-ENGLISH.

ABSTRACT: PESTAB. The effect of phthalophos (Ph) on the embryogenesis of 13 albino rats and 650 embryos was studied to collect data concerning pesticide metabolism in animals and embryos, and the relationship between the embryotoxic properties of the compound and its dosage and reaction time. The toxin (0.3-15 mg/kg/day, 0.0002-0.1 LD50) was injected via the gastrointestinal tract for the duration of pregnancy. The effect of Ph on embryogenesis was measured after death of the embryos or by developed anomalities. Ph was found to have an embryotoxic effect in dosages non-toxic to the mother. When administered in large doses it had teratogenic features. The embryotoxic effect was due to changes in the molecular structure and to the formation of phthalomides during metabolism.

Two general models were obtained. The first model was derived for a structurally representative set of 68 chems. (R2=0.76, s=0.44), whereas the second involved a total of 344 compds. (R2=0.76, s=0.41). The first was validated using the data for the remaining 276 pollutants (R2=0.70, s=0.45). An addnl. validation of both models was performed using an independent set of 48 pollutants. Both models predict the logKOC at the level of exptl. precision, while the theor. mol. descriptors appearing in the QSPR models give further insight into the mechanisms of soil sorption. The anal. of the distribution of the residuals of the logKOC values calcd. by both general models indicated the need and possible advantages of modeling soil sorption for smaller

data sets related to individual classes of chems. Accordingly, QSPR models were also developed for 14 chem. classes. The descriptors appearing in these models were discussed as related to the possible interaction mechanisms in soil sorption. [on SciFinder (R)] 0095-2338 QSPR/ model/ sorption/ soil/ org/ pollutant

630. Kalbitz, K. and Wennrich, R. (Mobilization of Heavy Metals and Arsenic in Polluted Wetland Soils and Its Dependence on Dissolved Organic Matter. *Sci total environ. 1998, jan 8; 209(1):27-39. [The science of the total environment]: Sci Total Environ*.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: The wetland soils of the Mulde river in the industrial district of Bitterfeld-Wolfen (Germany) are highly contaminated with heavy metals and arsenic. We studied the mobility of accumulated heavy metals and arsenic and the influence of dissolved organic matter (DOM) on element mobility. Undisturbed soil cores were taken from five different sites to represent a wide range of heavy-metal contamination, soil properties and dissolved organic carbon (DOC) concentrations. The acid-soluble concentrations (mostly equal to the total content) were up to 1100 mg kg-1 for Zn, 800 mg kg-1 for Cr, 364 mg kg-1 for Cu, 265 mg kg-1 for As and 37 mg kg-1 for Hg, depending on the sampling site. Percolation experiments using small lysimeters with undisturbed topsoil cores illustrated a considerable mobilization of Zn, Cd, Cu, Cr and Hg, depending on soil properties. Up to 80 micrograms l-1 Cd, 8 mg 1-1 Zn, 130 micrograms l-1 Cr, 160 micrograms l-1 Cu and 7 micrograms l-1 Hg were detected in the soil percolates. Arsenic mobilization was low. The concentration of Cr, Hg, Cu and As in the soil percolates was positively correlated with DOM. Besides the element content (mobile or acid-soluble), soil pH and soil characteristics describing the soil potential for heavy-metal adsorption (clay, oxides, cation exchange capacity), the DOC concentration in the soil solution should be known to access the potential mobilization of Hg, Cr, Cu and As. In contrast, Cd and Zn mobilization depends on soil pH and mobile element content, but not on DOM. Additional studies on two soil profiles (down to 1.5 m) confirmed the translocation of heavy metals from the highly contaminated topsoil into deeper soil horizons and into the groundwater and the influence of DOM as revealed with the percolation experiment. Our results also showed that DOM is of minor importance on the mobilization of heavy metals in soils with a low soil pH ($<$ 4.5).

The combined advantages of selectivity offered by the microparticle-packed stationary phase and variable solvating power of the supercrit. fluid are fully utilized in this approach. The greater sample loadings and lower detection limits possible using packed columns (based on concn. of sample in the injection solvent) compared with com. available capillary columns are demonstrated for the detn. of a series of organophosphorus insecticides. Low concns. of polar fluid modifiers, generally required for high-quality sepns. in packed-column SFC, also function as mild chem. ionization reagents. Broad classes of thermally labile, higher mol. wt., moderately polar pesticides are amenable to identification by SFC-MS, which provides a sensitive, selective, and broadly applicable technique for the identification of pesticide compds. with detection limits in the part-per-billion range. The Netherlands' Uniform System for Evaluation of Substances (USES, Version 1.0) has been applied in order to est. the Predicted Environmental Concns. (PECs) in surface water for set of pesticides mainly used in the Danube region. Based on the obtained Hazard Quotients priority list have been performed according the potential of the pesticides to cause short- and long-term effects to the aquatic organisms. The results provide information for decision making support and elaboration of redn. programs for aquatic environment. The study operated from 1982 to 1991. During that time 37 market baskets, each contg. 234 food items that represented about 5000 food types in American diets covering all age groups, including infants and children, were collected. Each food item was individually prepd. for eating; i.e., it was opened, unwrapped, washed, peeled, sliced, formulated by recipe, or cooked. Each item was then composited and anal. screened for about 300 different chems., including chlorophenoxy acids, ethylenethiourea, Me carbamates, organochlorines, organophosphates, organosulfurs, phenylureas, and pyrethroids. Overall, less that 1% of the potential of 2.5 million findings occurred for the 10-yr study period. In total, 138 different chem. residues accounted for 17,050 accumulated findings. Most findings were less than 1 mg/g, which is considered a low-level finding. Each food item averaged about 2 low-level findings per anal. ABSTRACT: PESTAB. The toxicity and accumulation of phthalophos in young carp and other fish were studied in aquariums. The LC50 was found to be 4.4-4.8 mg/liter for the different species. There were no deaths among carp kept in water with 1/50 LC50. Depression, disorientation, increased intestinal peristalis, loss of appetite, motor dyscoordination, tremor and spasms of the skeletal muscles, adynamia, paralysis, and depression of respiration were the symptoms of acute poisoning. Chronic poisoning with 1/5-1/10 of LC50 caused loss of appetite, depression, loss of equilibrium, and spasms of the skeletal muscles. Acute and chronic poisoning caused reduction of the hemoglobin level by 17%, of the erythrocyte count by 55.3%, of the hematocrit value by 13.1%, leukopenia, and vaculization of the cytoplasm of the erythrocytes. Acute and chronic poisoning caused inhibition of the acetylcholinesterase activity by 87.4-89% in the blood and by 41-85.6% in the brain. In chronic poisoning, considerable enzyme inhibition was seen even in the absence of clinical symptoms of poisoning. The residue levels after acute poisoning were 16.6 mg/kg in the kidneys, 14.6 mg/kg in the blood, 10.3 mg/kg in the intestinal wall, and 8 mg/kg in the muscles. No residues were found in the fish 8 days after poisoning, but phthalophos peristed for 4 months in deep-frozen meat.

Chem Codes: Chemical of Concern: PSM Rejection Code: NON-ENGLISH.

ABSTRACT: PESTAB. Clinical manifestations and diagnosis of poisoning of several fresh-water fishes by organo phosphorous pesticide phosmet were studied. The LD50 for Cyprinus, Hypophthalmichthys, and Leucaspius was 4.8, 4.4 and 4.7 mg/l, respectively. The larvae of Cyrinus were 1.5 times more sensitive to the exposure than were mature carps. Chronic exposure to pesticide at 0.2-0.033 LD50 resulted in the death of 50% and 8.3% of the carp. Characteristic features of both acute and chronic poisoning were marked inhibition of acetyl cholinesterase activity (87-89%), disturbances of the central and peripheral nervous system, adynamia, and convulsions. The content of the phosmet in organs and tissues were determined by means of TLC. In acute poisoning maximum concentration of the pesticide was detected in the kidneys (16.6 mg/kg), blood 14.6 mg/kg, intestinal wall (10.3 mg/kg), liver (10 mg/kg), gills (10.8 mg/kg and muscles (8.0 mg/kg). zeolite were prepd. and spectroscopically analyzed. Both exptl. and theor. results show the presence of silver nanoclusters with various sizes and environments in the zeolite hosts. The study indicates that the low energy emission mode (at 520 nm) was gradually activated and the high energy mode (at 415 nm) was deactivated upon increasing the excitation wavelength from 250 to 300 nm. The catalyzed system increases the photodecompn. of phosmet in comparison with the uncatalyzed expt. upon irradn. with different UV lights. Moreover, the largest catalytic activity was obsd. upon the irradn. of the catalyzed soln. with 302 nm where an increase in the decompn. rate by 40-fold was obsd. The photodecompn. products are similar for all systems but variations in the relative amt. of these products were obsd. at different conditions. Both catalyzed systems indicate the formation of phosphorothionic acid as the major product. Abstract: Using a combination of soaking data and an analytical solution of the diffusion equation, moisture diffusion coefficients of single wheat kernels were determined for nine commercial varieties representing Six market classes of U.S. wheat. Two geometric conditions, the whole kernel as a prolate spheroid, and the endosperm (also modeled as prolate spheroidal) and pericarp as separate components, were examined. Values from the analytical solution for a sphere were adjusted by a geometrical correction factor to more closely represent the response of a prolate spheroid. The ranges in diffusion coefficients were 0.39 x 10⁻¹⁰ to 1.04 x 10⁻¹⁰ m²/s for endosperm and 0.04 x 10⁻¹⁰ to 0.28 x 10⁻¹⁰ m²/s for pericarp. Compared to the pericarp, moisture diffused more rapidly in the endosperm. Soft wheats tended to have a more permeable pericarp layer than hard wheats, which resulted in a greater overall rate of diffusion, despite the endosperm of these two groups being nearly equivalent in diffusion coefficient value.

A specific and effective procedure including solid phase extn. in combination with HPLC and GC anal. methods were applied. Samples that were sensitive to nitrogen-phosphorus (NPD) and/or electron capture (ECD) detectors were analyzed by capillary gas chromatog. From the twenty-six water samples, pesticide residues were detected in fourteen of them (54%) but no one exceeding the European Union Maximum Acceptable Concn. (MAC). Lindane (g-BHC) was the most frequently detected pesticide. It was found in nine samples (35%) in concns. from <0.005 to 0.01 mg/L. Other pesticides detected were phorate (in five samples), propachlor (in two samples) and chlorpyrifos Et (in three samples), but in concns. far below the permissible levels. chem. structures were theor. estd. by using parameters derived from their mol. geometries and electronic properties calcd. with the MNDO-PM3 semiempirical SCF method. The multiple regression anal. showed that the logP values were satisfactorily expressed by van der Waals vol., total no. of hydrogen bonding sites, and the LUMO energy. The equation correlated very well the logP values measured. Although the accuracy of the prediction is slightly lower than that of the CLOGP procedure, the method can est. the logP values for the pesticides which could not be calcd. by CLOGP because of the lack of the related fragment values. A two-parameter correlation was found for class 1 toxins with R2 = 0.96, and a five-parameter correlation was found for class 2 toxins with R2 = 0.92. A five-parameter correlation for class 3 toxins had R2 = 0.85. The correlations for class 4 toxins were less satisfactory. All the descriptors utilized are calcd. solely from the structures of the mols., which makes it possible to predict unavailable or unknown toxins. [on SciFinder (R)] 0095-2338

644. Kaufman, Aaron, Bar-Matthews, Miryam, Ayalon, Avner, and Carmi, Israel (2003). The vadose flow above Soreq Cave, Israel: a tritium study of the cave waters. *Journal of Hydrology* 273: 155-163.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

32 tritium analyses were performed on 13 different water sources within Soreq Cave, Israel; eight of the water sources were analyzed once each, and the other five between 3 and 6 times each, on samples collected between 1990 and 2000. The results were compared with similar analyses of a 1981-82 collection and with the tritium concentrations of the annual rainfall from 1952 to 1998. The tritium in several of the cave waters was so high (up to 110 TU) that they must have originated mainly in the peak tritium rain year 1964. Most of the other cave waters had tritium concentrations, which though somewhat lower, must have originated largely from rain that fell between 1962 and 1966. The consequences of these tritium observations are that: (1) it generally takes 26-36 years for rainwater to percolate from ground surface to Soreq Cave ceiling; and (2) the type of flow undergone during this percolation is in several cases very similar to `piston flow', hence the annual packets of rainfall reach the cave without undergoing much mixing with either earlier or later rains. In about one-third of the cases, tritium was too low to determine the percolation time. Finally, the time variations of the tritium concentrations in specific cave water sources seem to indicate that the conduits which bring water to these sources may have undergone physical changes which affect the amount of time it took for rain to reach the cave ceiling.

645. Kawade, Yoshimi and Watanabe, Itaru (1956). Sedimentation study of sodium deoxypentosenucleate preparations from herring sperm and calf thymus. *Biochimica et Biophysica Acta* 19: 513-523.
Chem Codes: Chemical of Concern: PSM Rejection Code: IN VITRO.

Sedimentation coefficients s20, w of five preparations of sodium deoxypentosenucleate (DNA) purified from hearing sperm and one from calf thymus were measured by a Spinco ultracentrifuge at concentrations below 0.5%. Limiting viscosity numbers [[eta]] of these preparations were determined using capillary viscometers of relatively low velocity gradient. Marked variation of s20, w and viscosity from preparation to prepapation was observed. Sedimentation coefficients at zero concentration, s0 (in Svedbergs), were found to be 8.0, 8.4, 8.6, 10.0 and 19 for herring sperm DNA in sodium phopshate buffer of ionic strength 0.2 at pH 7.7, and 23 for calf thymus preparation in 0.2 M sodium chloride (s0 values of herring DNA preparations are probably about 10% lower than true ones because of the secondary charge effect). Among the herring DNA samples, four were obtained from soft roes stored frozen for not less than several weeks, and one from fresh material. The calf thymus preparation was obtained from very fresh material. The latter two preparations, which will be in the least degraded state, possess the highest s0 values, which exceed all values hitherto reported for DNA (12-15S) except those of . Plot of log s0 [[eta]] gives a straight line with a slope of 0/38. This definitely higher than the slope expected for unhydrated, rigid, prolate ellipsoids of revolution with constant minor axis, and therefore such a model is inadequate for DNA. If, instead, a coil model is assumed, it should be fairly stiff judging from the value of the exponent of the modified Staudinger rule, estimated to be 0.9 from the slope of log s0 vs. log [[eta]] plot. The samples with lower so and [[eta]] are probably considerably heterogeneous with respect to molecular weight, judging from the sedimentation patterns. Rapidly sedimenting "gel component" or "insoluble fraction" was not detected in any case. When 1/s20, w is plotted against concentration, the resulting curve is concave toward the concentration axis. The ratio of Ks, a constant characterizing the slope of this curve at infinite dilution, to [[eta]] was found to be fairly constant with these preparations, averaging about 0.8.

A description of the 100 MHz. N.M.R. of 40 organophosphorus pesticides is presented as an identification aid and reference source. Chem. shifts and coupling consts. are presented. Trends in chem. shifts and coupling consts. as related to structure are included. Homonuclear spin decoupling, integration, protonation with F3CCO2H, D2O exchange, temp., solvent and diln. effects, and supplemental 60 MHz. spectra all were employed in correlating the spectra with the structures of the corresponding mols. Interesting phenomena observed include long-range P to H coupling through four and five bonds, chem. nonequivalence of methylene groups and Me groups in (EtO)2P and (MeO)2P moieties, differences in the spectra of the cis and trans isomers of 2 pesticides due to anisotropic effects of their carbonyl groups, and magnetic nonequivalence of geminal methylene protons adjacent to an asymmetric C atom. 22 references. Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

Two amber mutations in gene 67 of bacteriophage T4 were constructed by oligonucleotide-directed mutagenesis and the resulting mutated genes were recombined back into the phage genome and their phenotype was studied. The 67amK1 mutation is close to the amino terminus of the gene, and phage carrying this mutation are unable to form plaques on suppressor-negative hosts. A second mutation, 67amK2, which lies in the middle of the gene, three codons N-terminal to a proteolytic cleavage site, produces a small number of viable phage particles. In suppressor-negative hosts, both mutants produce poly heads and proheads. 67amK1 assembles only few proheads that have a disorganized core structure, as judged from thin sections of infected cells. The proheads and the mature phages of both mutants are mainly isometric rather than having the usual prolate shape. Depending on the 67 mutant and the host, between 20% and 73% of the particles that are produced are isometric, and 1 to 10% are two-tailed biprolate particles. 67amK2 phages grown on a supD suppressor strain that inserts serine in place of the wild-type leucine do not contain gp67* derived from gene product 67 (gp67) by proteolytic cleavage. This demonstrates the importance of the correct amino acid at this position in the protein. Other abnormalities in these 67amK2 phages are the presence of uncleaved scaffolding core proteins (IPIII and gp68), indicating a structural alteration in the prohead scaffold, resulting in only partial cleavage. In wild-type phages these proteins are found in the head only in the cleaved form. With double-mutants of 67 with mutations in the major shell protein gp23 no naked scaffolding cores were found, confirming the necessity of gp67 for the assembly or persistence of a "normal" core.

651. Keller, Beat, Sengstag, Christian, Kellenberger, Edward, and Bickle, Thomas A. (1984). Gene 68, a new bacteriophage T4 gene which codes for the 17K prohead core protein is involved in head size determination. *Journal of Molecular Biology* 179: 415-430.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

We have identified the gene for a major component of the prohead core of bacteriophage T4, the 17K protein. The gene, which we call gene 68, lies between genes 67 and 21 in the major cluster of T4 head genes. All of the genes in this region of the T4 genome have overlapping initiation and termination codons with the sequence T-A-A-T-G. We present the DNA sequence of the gene and show that it codes for a protein containing 141 amino acids with an acidic aminoterminal half and a basic carboxyl terminus. Antibodies prepared against the 17K protein were used to show that it is cleaved by the phage-coded gp21 protease during head maturation and that most of the protein leaves the head after cleavage. A frameshift mutation of the gene was constructed in vitro and recombined back into the phage genome. The mutated phages had a drastically reduced burst size and about half of the particles produced were morphologically abnormal, having isometric rather than prolate heads. Thus, the 17K protein is involved in head shape determination but is only semi-essential for T4 growth. http://www.sciencedirect.com/science/article/B6WK7-4FNGD09-5W/2/4a56b3275761478996233bbad6ff9704

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Mossbauer spectra of deoxymyoglobin, deoxyhemoglobin, and the synthetic analogues, iron (II) 2-methylimidazole meso-tetraphenylporphyrin, and iron (II) 1,2-dimethylimidazole meso-tetraphenylporphyrin have been observed in high magnetic fields and over a wide range of temperature. At temperatures greater than 20 K all materials exhibit remarkably similar spectra, with anisotropic internal magnetic fields decreasing as 1/T. All have negative quadrupole interaction, and both this and the magnetic anisotropy imply that the orbital of the odd electron is prolate in the ground quintet, with little unquenched orbital angular momentum. At 4.2 K the spectra differ, suggesting different detailed structure within the quintet. In contrast to the proteins, the 2-methyl model exhibits spectra at 4.2 K which imply that the lowest spin state has high susceptibility in a single direction. The designed biosensor contains a ferromagnetic core passivated by an epoxide cover in a high-frequency elec. field. Complexing agent mol. with an 8-hydroxyquinoline region is covalently bound to the cover and serves for strong fixation of aluminum hydroxide. This compn. \"Magnosorb\" binds with the enzyme butyrylcholinesterase. Such a biosensor has high sensitivity to inhibition by organophosphate pesticides (up to 20-50 ng per mL). Various environment and food compds. can be tested without laborious preliminaries. However, the sensor's ability for inhibition is gradually decreased when the full component is stored, whereas esterase activity is more stable. This phenomenon is called \"Functional Disadequacy\", and can be cor. with the help of a \"Binary Sensor\" technique, in which the sensor is made up of two parts (carrier \"Magnosorb\" and fresh dissolved enzyme) just before use. The proposed method can be used in broad inspection monitoring of an \"Alarm Signal\". [on SciFinder (R)] 0003-2719 ferromagnetic/ biosensor/ assay/ organophosphate/ pesticide

655. King, Richard J., Simon, Dexter, and Horowitz, Paul M. (1989). Aspects of secondary and quaternary structure of surfactant protein A from canine lung. *Biochimica et Biophysica Acta (BBA) - Lipids*

and Lipid Metabolism 1001: 294-301.
Chem Codes: Chemical of Concern: PSM Rejection Code: IN VITRO.

The results of a large number of studies indicate that pulmonary surfactant contains a unique protein whose principal isoform has a molecular weight of about 30 000, and whose presence in surfactant is associated with important metabolic and physicochemical properties. This protein, SP-A, as isolated from canine surfactant, contains a domain of 24 repeating triplets of Gly-X-Y, similar to that found in collagens. These studies were undertaken to determine whether SP-A forms a collagen-like triple helix when in solution, and to describe certain aspects of its size and shape. Our experiments were done on SP-A extracted by two different methods from canine surfactant, and on SP-A produced by molecular cloning. The results from all three preparations were similar. The circular dichroism of the complete protein was characterized by a relatively large negative ellipticity at 205 nm, with a negative shoulder ranging from 215 to 230 nm. There was no positive ellipticity, and the spectrum was not characteristic of collagen. Trypsin hydrolysis resulted in a fragment with peak negative ellipticity at about 200 nm, without the negative shoulder. Further hydrolysis of this fragment with pepsin resulted in a CD spectrum similar to that of collagen. The spectrum of the collagen-like fragment was reversibly sensitive to heating to 50[degree sign]C, and was irreversibly lost after treatment with bacterial collagenase. SP-A migrated on molecular sieving gels with an equivalent Stokes radius of 110 to 120 A, and had a sedimentation coefficient of 14 S. Using these data we calculate a molecular weight of about 700 000. The hydrodynamic characteristics can be approximated as a prolate ellipsoid of revolution having an axial ratio of about 20. We conclude that SP-A aggregates into a complex of 18 monomers, which may form six triple-helices. The shape of the complex is considerably more globular than collagen and is not consistent with end-to-end binding of the helices to form fibrous structures. ABSTRACT: PESTAB. Organic phosphorus insecticides may cause human chromosome mutations in persons with severe acute intoxication. In order to obtain data on the genetic effect of prolonged occupational exposure to small doses a study was initiated on workers producing and formulating organic phosphorus insecticides in the Budapest Chemical Works. On the one hand the chromosomes of O-control (49 persons), industrial control (14 persons), positive control (tetrachlorobenzene, 25 persons) and three organophosphate insecticide groups (trichlorfon, 17 persons; diazinon, 34 persons; phosmet, 25 persons) were studied in peripheral blood cultures. The frequency of chromatid-type aberrations in all organophosphate groups was higher than in controls. Occurrence of stable chromosome-type aberrations was higher in the diazinon group. On the other hand a genetic-epidemiologic survey has been made of nearly 2000 workers. Evaluation of data is in process. (Author abstract by permission)

658. Kiryushina, L. P. (Chromatographic Determination of Basudin Residues in Soil, Water, and Fish. *Khim. Sel. Khoz. 14(12): 54* 1976..
<u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: NON-ENGLISH.

ABSTRACT: PESTAB. Thin-layer chromatographic method for the determination of basudin (diazinon) in soil, water, and fish is described. After extraction with n-hexane, the residue is determined on a silica gel plate, using an n-hexane- acetone mixture (9:1) as a solvent system. The plate is sprayed with bromphenol blue and silver nitrate solutions, and then with 2% citric acid or 5% acetic acid solution for background color suppression. Diazinon forms dark blue spots against a yellow background. The sensitivity of the method is 2 mu in the water sample and 5mu in soil and fish. The Rf value of diazinon is 0.35, that of its metabolite is 0.14. Fenthion, methyl parathion, ronnel, dimethoate, dichlorvos, phosalone, and fenitrothion do not interfere with the determination, but trichlorfon and phthalophos (phosmet) do.

659. Klaij, M. C. and Vachaud, G. (1992). Seasonal water balance of a sandy soil in Niger cropped with pearl millet, based on profile moisture measurements. *Agricultural Water Management* 21: 313-330.
<u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: FATE.

In the Sahel, calculation of the field water balance from neutron-probe measurements is often difficult for pearl millet (Pennisetum glaucum (L.) R. Br.), which is due to the rapid drainage (D) of the sandy soils, on which it is typically grown. We present a simple method of calculating D in these soils from weekly neutron-probe data. The method divides the water balance into two phases. In the first, applicable early in the season, water flux across the maximum depth of probe measurement (Zm) is assumed negligible, and evapotranspiration (E) and D are calculated from the change in soil water content ([theta]) between the bottom of the rootzone (Zr) and Zm, thus allowing calculation of unsaturated hydraulic conductivity, K([theta]), from the flux across Zr. In the second phase, when soil water starts to percolate across Zm, D is calculated from K([theta]), assuming a hydraulic head gradient of -1. The method is used to calculate a one-dimensional water balance of a pearl-millet crop grown in a deep sandy soil at two fertility levels during a season of normal rainfall. Results show that the calculated K([theta]) functions compare well with those based on laboratory measurements. An acceptable estimate of drainage, and therefore E could be made. Mean cumulative E and D were, respectively, 211 and 207 mm for the unfertilized crop, and 268 and 148 mm for the fertilized crop with 440 mm of rainfall received during the crop cycle. The fertilized millet crop water balance was simulated, which compared to the calculation method resulted in an about 10% higher seasonal E and a 10% lower seasonal D. Our study shows that E can be corrected for D using a simple but accurate method, and consistent with other studies in the region indicates that rainfall is usually not the primary limiting factor to pearl-millet production. http://www.sciencedirect.com/science/article/B6T3X-488G267-

661. Kligerman, M. M., Liu, T., Liu, Y., Scheffler, B., He, S., and Zhang, Z. (Interim Analysis of a Randomized Trial of Radiation Therapy of Rectal Cancer With/Without Wr-2721. *Int j radiat oncol biol phys. 1992; 22(4):799-802. [International journal of radiation oncology, biology, physics]: Int J Radiat Oncol Biol Phys.*
Chem Codes: Chemical of Concern: PSM Rejection Code: HUMAN HEALTH.

ABSTRACT: The objectives of this randomized trial are to define the maximum tolerated dose of radiation therapy, at curative dose levels, that can be delivered following WR-2721, and to observe the anti-tumor effects and normal tissue responses. One hundred patients with inoperable, unresectable, or recurrent rectal cancer were stratified and randomized to radiation only, or WR-2721 and radiation. The entire pelvis is treated with 4 portals 4 times a week to a total of 4500 cGy (first level dose) in 5 weeks. WR-2721, 340 mg/m2 was given 15 minutes before radiation to the combination group. Subsequently, both groups received a conedown of 720 cGy in 4 days to 144(2) cm portals APPA, and if originally inoperable or unresectable 720 cGy in four days to second conedown of 64(2) cm. Patients were observed from 3 to 18 months (median = 12 months). No significant hypotension or hematologic toxicity occurred in the WR-2721 treated group. Mild to moderate emesis occurred in 80% of the courses. (No antiemetics were used.) Moderate or severe acute toxicities to normal tissues were observed less frequently in the WR-

2721 arm. No moderate or severe late toxicities to the skin, mucous membrane, urinary bladder or intestine was observed in the WR-2721 group, however, 5 patients treated with radiation alone experienced moderate or severe late toxicity to these organs. No evidence of tumor protection was observed.

Abstract: Pollen grains of 9 species of the genus Plantago (Plantaginaceae), including 8 taxa native to Poland, were observed under a light microscope and a scanning electron microscope. Descriptions of grain sculpture are illustrated only SEM micrographs. The studied pollen grains were medium-sized or small, spherical or prolate spheroidal. Their sculpture was always verrucate with granulation. In the studied taxa, internal apertures had the form of pores. Their number ranged from (4)5-9(14). The pores were scattered on the surface of pollen grains. Identification features of individual taxa include: presence or absence of an annulus around each pore, annulus structure, ornamentation of the pollen grain and operculum, type of aperture membrane, number of internal pores, and pore diameter. We suggest that two new pollen grain types, characteristic of P. intermedia and P. arenaria, should be distinguished, and that P. alpina should be assigned to the P. coronopus type.

ABSTRACT: PESTAB The effect of UV radiation in the wavelength range of 250-400 nm on the decomposition of phencapton, phthalophos (phusmet), sayfos (menazon), phosalone, and cidial (phorate) was studied by UV spectrometry and enzyme thin-layer chromatography. The photochemical decomposition of the dialkyldithiophosphates can be described kinetically by a first-order reaction. The half-lives of phencapton, cidial, phosalone, phthalophos, and sayfos were 12, 11, 86, 70, and 630 min. Decomposition, primarily through oxidation of the P-S group, is assumed. Phthalimide, P-O analogs, N-oxymethylphthalimide, and phthalic acid were identified as the decomposition products of phthalophos.

Abstract: To study the impact of changes in groundwater flow and chemistry on acidity export from sediments in acid mine drainage (AMD) polluted lakes, a column experiment was carried out. Schwertmannite rich sediment was subjected to three different flow rates (0, 5, and 20 L m super(-2) a super(-1)), two percolate chemistries (1/1 mmol L super(-1) vs 10/15 mmol L super(-1) sulfate/ferrous iron, pH 5), and DOC input (similar to 2.5 mmol C L super(-1)). Percolation induced acidity export in all percolated treatments (8.8-40.4 mol m super(-2) a super(-1)) by accelerated proton generation from schwertmannite transformation (18.0-35.9 mol m super(-2) a super(-1)) and ferrous iron release (3.8-11.6 mol m super(-2) a super(-1)) from the sediment

matrix. Mobilization increased with flow rate and decreased with sulfate and iron concentrations. Unspecifically bound ferrous iron contents increased within the sediment (up to 40.5 mol m super(-2) a super(-1)) when iron concentrations in the percolate were high. Reduced sulfur species formed following raises in pH, but acidity consumption through this process (0.3-6.6 mol m super(-2) a super(-1)) and the formation of carbonates (0.11-0.45 mol m super(-2) a super(-1)) remained small. The study thus suggests that increases in groundwater inflow remobilize acidity from AMD polluted sediments.

667. Koch, Arthur L. (1992). Differences in the formation of poles of Enterococcus and Bacillus. *Journal of Theoretical Biology* 154: 205-217.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

The pole of Enterococcus hirae (Streptococcus faecium) is more pointed than that of Bacillus subtilis; i.e. the pole of the former is prolate and the latter is oblate. Both species form their poles by constructing annular additions on the inside surface. In both cases, the thick septum starts to split from the outside before the septum is complete. Physiochemical considerations dictate that the peptidoglycan must be unstretched as laid down. However, it later becomes stressed and may stretch to increase its surface area or to change its shape. Our earlier analysis for B. subtilis demonstrated that, without the addition of new peptidoglycan, the nascent wall is stretched after it is externalized to 1[middle dot]51 times the original area. The wall of partially formed poles that is already exteriorized continues to deform with further development. For E. hirae, Higgins & Shockman's measurements showed that the completed pole has a surface area 2[middle dot]18 times larger than a completed septal disk and the wall changes shape very little after

exteriorization. A model is presented here for the streptococcus in which the septal wall does not increase its surface area on exteriorization either by expansion or by murein insertion. Instead, the septal wall as it is split and exteriorized twists to become oblique, increasing the inner radius of the incomplete septum. In consequence of this rotation, extra layers of peptidoglycan are added to the inside face of the developing septum. This additional murein forms the more pointed pole shape for E. hirae. This "split-and-splay" model thus refines and extends the surface stress theory of E. hirae developed a decade ago by proposing a source of the extra wall needed for the formation of its prolate, more pointed, pole.

Citations: 49) Mattern, G; J Assoc Anal Chem 1991, 74, 982 The authors developed a new instrumental approach, termed Supersonic GC-MS, which achieves fast, sensitive, confirmatory and quant. anal. of a broad range of pesticides in complex agricultural matrixes. This Supersonic GC-MS system is a modification of a bench-top Agilent 6890 GC+5972 MSD with a supersonic mol. beam (SMB) interface and fly-through EI ion source. One of the main advantages of Supersonic GC-MS is an enhanced mol. ion (M+) in the resulting mass spectra. For example, the

M+ was obsd. in all 88 pesticides that were studied using the Supersonic GC-MS, whereas only 36 of 63 (57%) pesticides that were investigated in std. GC-MS exhibited a M+. Also, the degree of matrix interference was exponentially reduced with the fragment mass by about 20-fold per 100 amu increasing mass. The enhancement of the M+ combined with the redn. in matrix background noise permit rapid full scan anal. of a potentially unlimited no. of pesticides, unlike selected ion monitoring or MS-MS in which specific conditions are required in segments for targeted pesticides. Furthermore, unlike the case with chem. ionization, EI-SMB-MS spectra still give accurate identification of compds. using common mass spectral libraries. In practice, libraries favor mass spectra in which the M+ appears; thus, Supersonic GC-MS produced better spectra for compd. identification than std. GC-MS. To achieve even lower identification limits, the M+ plus a second major ion (still using full scan data) gives higher signal-to-chem. noise ratios than the traditional 3-ion approach. The replacement of two low-mass ions with the M+ (supersonic two-ions method) results in a significant redn. of matrix interference by a factor of ?90. Another main advantage of Supersonic GC-MS is its exceptional suitability for fast GC-MS with high carrier gas flow-rate. Fast Supersonic GC-MS was able to det. thermally labile pesticides, such as carbamates, that are difficult or impossible to det. in std. GC-MS. Large vol. injection using a ChromatoProbe was also demonstrated, in the 6-min anal. of a spice matrix for pesticides at 20 ng/g. Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. A method for screening of pesticide-contaminated soil was developed. The extraction is carried out by supercritical carbon dioxide (CO_2) with methanol as a modifier. The different components of the extracts are separated by high-performance thin-layer chromatography with automated multiple development (HPTLC) and evaluated densitometrically. The technique can be carried out without any previous clean-up step. Compared with other extraction techniques, SFE has the advantages of reducing the amount of co-extracted soil contents, which can seriously deteriorate the results. A 35-step development of the TLC-plate with gradient elution offers an application over a wide range of polarity. Migration data for 107 pesticides, recoveries and detection limits for 20 pesticides were determined.

670. Koenig, Virgil L. and Perrings, J. D. (1952). Critical sedimentation and viscosity studies on crystalline bovine plasma albumin. *Archives of Biochemistry and Biophysics* 41: 367-377.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Ultracentrifugal and viscosity studies have been carried out on crystalline bovine plasma albumin at various temperatures using 0.2 M NaCl as solvent. Ultracentrifugal studies on crystalline bovine plasma albumin dissolved in 0.2 M NaCl have been carried out using three different speeds. There would appear to be a progressive increase in the value of the sedimentation constant at zero concentration with increase in temperature. The differences in the intercepts are statistically significant for a difference of ten degrees in temperature. This fact would indicate the failure of the correction formula when the temperature is ten degrees from 20 [degree sign]C. There is a progressively small decrease in sedimentation constant at zero concentration with an increase in the speed of rotation. Volume intrinsic viscosity was calculated, and from it, by use of the Simha and Perrin equations and the sedimentation constant, assuming the molecule to be a prolate ellipsoid, the molecular weight was found to be 64,500. The diameter and length were found to be 31.22 A. and 152.67 A., respectively. This agrees with values determined by other methods.

Citations: Welch, R; Toxicol Appl Pharmacol 1969, 14, 358 The authors tested 200 pesticides, including some of their isomers and metabolites, for agonism and antagonism to two human estrogen receptor (hER) subtypes, hERa and hERb, and a human androgen receptor (hAR) by highly sensitive transactivation assays using Chinese hamster ovary cells. The test compds. were classified into nine groups: organochlorines, di-Ph ethers, organophosphorus pesticides, pyrethroids, carbamates, acid amides, triazines, ureas, and others. These pesticides were tested at concns. < 10-5 M. Of the 200 pesticides tested, 47 and 33 showed hERa- and hERb-mediated estrogenic activities, resp. Among them, 29 pesticides had both hERa and hERb agonistic activities, and the effects of the organochlorine insecticides b-benzene hexachloride (BHC) and d-BHC and the carbamate insecticide methiocarb were predominantly hERb rather than hERa agonistic. Weak antagonistic effects toward hERa and hERb were shown in five and two pesticides, resp. On the other hand, none of tested pesticides showed hAR-mediated androgenic activity, but 66 of 200 pesticides exhibited inhibitory activity against the transcriptional activity induced by 5a-dihydrotestosterone. In particular, the antiandrogenic activities of two di-Ph ether herbicides, chlornitrofen and chlomethoxyfen, were higher than those of vinclozolin and p,p'-dichlorodiphenyl dichloroethylene, known AR antagonists. The results of our ER and AR assays show that 34 pesticides possessed both estrogenic and antiandrogenic activities, indicating pleiotropic effects on hER and hAR. The authors also discussed chem. structures related to these activities. Taken together, our findings suggest that a variety of pesticides have estrogenic and/or antiandrogenic potential via ER and/or AR, and that numerous other manmade chems. may also possess such estrogenic and antiandrogenic activities. The amidophosphates and thiophosphates were prepd. by 3 different methods, e.g., by treating the Na or K salt of the corresponding phenol with bis(dimethylamido)phosphate and thiophosphate in MeCN. The systemic insecticidal activity of I was lower than the activity of thiometon. I(X = S,R1 = 2-Cl, R2 = 4-NO2, R3 = R4 = H) [73094-17-4] was a more active acaricide than malathion and phosmet, but was less active than carbophenothion. O-8-Quinolylbis(dimethylamido)phosphate [73094-16-3] was the only I having fungicidal activity (against powdery mildew) higher than captan. None of the I had high herbicidal activity. 676. Konidala, Praveen, He, Lizhong, and Niemeyer, Bernd (2006). Molecular dynamics characterization of n-octyl-[beta]-d-glucopyranoside micelle structure in aqueous solution. *Journal of Molecular Graphics and Modelling* 25: 77-86.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

n-Octyl-[beta]-d-glucopyranoside (OG) is a non-ionic glycolipid, which is used widely in biotechnical and biochemical applications. All-atom molecular dynamics simulations from two different initial coordinates and velocities in explicit solvent have been performed to characterize the structural behaviour of an OG aggregate at equilibrium conditions. Geometric packing properties determined from the simulations and small angle neutron scattering experiment state that OG micelles are more likely to exist in a non-spherical shape, even at the concentration range near to the critical micelle concentration (0.025 M). Despite few large deviations in the principal moment of inertia ratios, the average micelle shape calculated from both simulations is a prolate ellipsoid. The deviations at these time scales are presumably the temporary shape change of a micelle. However, the size of the micelle and the accessible surface areas were constant during the simulations with the micelle surface being rough and partially elongated. Radial distribution functions computed for the hydroxyl oxygen atoms of an OG show sharper peaks at a minimum van der Waals contact distance than the acetal oxygen, ring oxygen, and anomeric carbon atoms. This result indicates that these atoms are pointed outwards at the hydrophilic/hydrophobic interface, form hydrogen bonds with the water molecules, and thus hydrate the micelle surface effectively. ABSTRACT: PESTAB. A thin-layer chromatographic method for the determination of phthalophos in pathological materials, feed, and plant materials is described. After extraction with acetone, coextracted impurities are eliminated by reextraction with water and chloroform, and the final specimen in acetone is applied to a silica gel layer, using a 2:1 mixture of hexane and acetone as solvent system. Bromphenol blue in acetone and an aqueous solution of silver nitrate are used for visualization. After the plate is sprayed with acetic acid solution, phthalophos appears in the form of dark blue spots against a yellowish background. The Rf value is 0.52+-0.03. The sensitivity of the method is 0.3 mg/kg at a recovery rate of 88+-11%.

ABSTRACT: PESTAB. Chinchilla rats were sacrificed 2 hours to 20 days after poisoning with 100 or 50 mg/kg oral doses of phthalophos (phosmet) to investigate the distribution of the poison in different organs. General depression, reduction of muscle tones, miosis, sialorrhea, tremor, fasciculation of the dorsal muscles, spasm of the limbs, dyspnea, cyanosis, and coma were observed. The acetylcholinesterase activity dropped by 87%. Passive hyperemia of the blood vessels of the brain and parenchymatous organs was revealed on autopsy. Phthalophos and an unidentified metabolite with Rf = 0.72 were found in the gastric content and in the liver of animals killed 2 hours after poisoning. Phthalophos was no longer detectable in the gastric content of animals killed more than 4 days after poisoning, while residues appeared on the fourth day in the skeletal muscles and brain. Normalization of the acetylcholinesterase activity and disappearance of phthalophos residues from the organs was observed in animals killed on the 20th day.

Abstract: Faecal sludge (FS) from the on-site sanitation systems is a nutrient-rich source but can contain high concentrations of toxic metals and chemicals and infectious micro-organisms. The study employed 3 vertical-flow CW units, each with a dimension of 5 x 5 x 0.65 m (width x length x media depth) and planted with cattails (Typha augustifolia). At the solid loading rate of 250 kg total solids (TS)/m super(2).yr and a 6-day percolate impoundment, the CW system could achieve chemical oxygen demand (COD), TS and total Kjeldahl nitrogen (TKN) removal efficiencies in the range of 80-96%. A solid layer of about 80 cm was found accumulated on the CW bed surface after operating the CW units for 7 years, but no clogging problem has been observed. The CW percolate was applied to 16 irrigation sunflower plant (Helianthus annuus) plots, each with a dimension of 4.5 x 4.5 m (width x length). In the study, tap water was mixed with 2O degree /o, 80% and 100% of the CW percolate at the application rate of 7.5 mm/day. Based on a 1 -year data in which 3 crops of plantation were experimented, the contents of Zn, Mn and Cu in soil of the experimental plots were found to increase with increase in CW percolate ratios. In a plot with 100% of CW percolate irrigation, the maximum Zn, Mn and Cu concentrations of 5.0, 12.3 and 2.5 mg/kg, respectively, were detected in the percolate-fed soil, whereas no accumulation of heavy

metals in the plant tissues (i.e. leaves, stems and flowers) of the sunflower were detected. The highest plant biomass yield and oil content of 1000 kg/ha and 35%, respectively, were obtained from the plots fed with 20% or 50% of the CW percolate.

ABSTRACT: Constructed wetlands (CWs) have been proven to be an effective low-cost treatment system, which utilizes the interactions of emergent plants and microorganisms in the removal of pollutants. CWs for wastewater treatment are ndrmally designed and operated in horizontal-flow patterns, namely, free-water surface or subsurface flow, while a vertical-flow operation is normally used to treat sludge or septage having high solid contents. In this study, three pilot-scale CW beds, each with a surface area of 25 m2, having 65 cm sand-gravel substrata, supported by ventilated-drainage system and planting with narrow-leave cattails (Typha augustifolia), were fed with septage collected from Bangkok city, Thailand. To operate in a vertical-flow mode, the septage was uniformly distributed on the surface of the CW units. During the first year of operation, the CWs were operated at the solid loading rates (SLR) and application frequencies of, respectively, 80-500 kg total solid (TS)/m2 x yr and 1-2 times weekly. It was found that the SLR of 250 kg TS/m2 x yr resulted in the highest TS, total chemical oxygen demand (TCOD) and total Kjeldahl nitrogen (TKN) removal of 80, 96 and 92%, respectively. The TS contents of the dewatered septage on the CW beds were increased from 1-2% to 30-60% within an operation cycle. Because of the vertical-flow mode of operation and with the effectiveness of the ventilation pipes, there were high degrees of nitrification occurring in the CW beds. The nitrate (NO3) contents in the CW percolate were 180-250 mg/L, while the raw septage had NO3 contents less than 10 mg/L. Due to rapid flow-through of the percolates, there was little liquid retained in the CW beds, causing the cattail plants to wilt, especially during the dry season. To reduce the wilting effects, the operating strategies in the second year were modified by ponding the percolate in the CW beds for periods of 2 and 6 days prior to discharge. This operating strategy was found beneficial not only for mitigating plant wilting, but also for increasing N removal through enhanced denitrification activities in the CW beds. During these 2 year operations, the dewatered septage was not removed from the CW beds and no adverse effects on the septage dewatering efficiency were observed.

ABSTRACT: In tropical regions, where most of the developing countries are located, septic tanks and other onsite sanitation systems are the predominant form of storage and pre-treatment of excreta and wastewater, generating septage and other types of sludges. The septage is disposed of untreated, mainly due to lack of affordable treatment options. This study presents lessons that have been learned from the operation of pilotscale constructed wetlands (CWs) for septage treatment since 1997. The experiments have been conducted by using three CW units planted with narrow-leave cattails (Typha augustifolia) and operating in a vertical-flow mode. Based on the experimental results, it can be suggested that the optimum solids loading rate be 250 kg TS/m2 yr and 6-day percolate impoundment. At these operational conditions, the removal efficiencies of CW units treating septage at the range of 80-96% for COD, TS and TKN were achieved. The biosolid accumulated on the CW units to a depth of 80 cm has never been removed during 7 years of operation, but bed permeability remained unimpaired. The biosolid contains viable helminth eggs below critical limit of sludge quality standards for agricultural use. Subject to local conditions, the suggested operational criteria should be reassessed at the full-scale implementation.

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Response of omegail and soil water of podzols in the Kola Peninsula to acid deposition was estimated under both field and laboratory conditions. A significant increasing trend of exchangeable acidity in organic (O) horizons and exchangeable Al in podzolic (E) horizons of podzols with distance from the nickel smelter was observed. The simulated rain at pH 4.5 did not alter chemical properties of soils and soil solutions. As much as 95-99% of the applied H+ ions were retained by soils and appeared in the percolates after a treatment period that depended on acid load and soil thickness. Ca and Mg in soil solutions were highly sensitive to acid loading. Simulated acid rain enhanced the leaching of exchangeable

base cations out of root zone. Acid inputs resulted in decreased pH, amount of exchangeable base cations and base saturation, in elevated exchangeable acidity and it's Al fraction in soil solid phase. The most significant changes occurred in O and E horizons. Substanti

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Recent studies have suggested that a fetal blood lead level of 0.48 mumol (much lower than 1.21 mumol/L, which is the level previously believed to be toxic to the developing brain) may impair brain development permanently. We measured the maternal and umbilical cord blood levels of lead and free erythrocyte protoporphyrin (FEP) among 95 consecutive mother-infant pairs to determine whether neonates in Toronto are in the high-risk group. There was a significant correlation between the maternal and the cord blood lead levels ($r = 0.59$, $p < 0.0001$). Most (99%) of the infants had cord blood lead levels below 0.34 mumol/L; in 11 cases the levels were below the detection limit of 0.01 mumol/L. The cord blood FEP levels were higher than the maternal levels The US Centers for Disease Control, Atlanta, currently finds acceptable a blood FEP level of 0.62 mumol/L among children up to 10 years of age; however, this is not applicable to newborns since their higher FEP levels appa

ABSTRACT: PESTAB. An enzyme chromatographic method for the rapid routine detection and

determination of organophosphorus pesticides in water and fish is described. After extraction with chloroform from water, and with acetone from fish, the extract is purified, and the thione phosphates are activated in hydrogen peroxide vapor. Organophosphorus pesticides as a group are visualized on chromatographic paper imbibed with a mixture of bromthymol blue and acetylcholinesterase. The sensitivity of the method amounts to 0.02 mg/kg in fish and to 0.002 mg/l in water for baytex (fenthion), DDVP (dichlorvos), phoxim, diazinon, trolen (ronnel), TCM-3, phosalone, and ciodrin; to 0.04 mg/kg in fish and 0.004 mg/l in water for methylnitrophos (fenitrothion), and to 0.1 mg/kg in fish and 0.01 mg/l in water for dursban (chlorpyrifos), carbophos (malathion), metaphos (methyl parathion), trichlorfon, and phthalophos (phosmet).

ABSTRACT: PESTAB. Fenitrothion (in the form of emulsifiable concentrates, wettable powder, and aerosol preparation for aerial application) was tested under field conditions in sown lucerne, cereals, rape, apple and pear-trees. Relatively high levels of fenitrothion are found, particularly in lucerne, even 13 days after aerial application of the aerosol (29. 9 mg/kg) or of the wettable powder (4. 9 mg/kg). The results of the analysis of the other crops indicate amounts not in excess of 0. 7 mg/kg which is the suggested tolerance in Czechoslovakia. Results on the persistence of phosmet in apples after the application of the emulsifiable preparation and the wettable powder ndicate that there are no apparent differences between the preparations and the applied concentrations (0. 1 and 0. 05% A). Since the residues are relatively low, it can be expected that their toxicological interpretation will be favorable. The determination of fenitrothion was based on gas chromatography using CsBröTID and that of phosmet on colorimetric enzymatic analysis.

691. Kraft, B. J., Masuda, S., Kikuchi, J., Dragnea, V., Tollin, G., Zaleski, J. M., and Bauer, C. E. (Spectroscopic and Mutational Analysis of the Blue-Light Photoreceptor Appa: a Novel Photocycle Involving Flavin Stacking With an Aromatic Amino Acid. *Biochemistry. 2003, jun 10; 42(22):6726-34. [Biochemistry]: Biochemistry*.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

ABSTRACT: The flavoprotein AppA is a blue-light photoreceptor that functions as an antirepressor of photosynthesis gene expression in the purple bacterium Rhodobacter sphaeroides.

Heterologous expression studies show that FAD binds to a 156 amino acid N-terminal domain of AppA and that this domain is itself photoactive. A pulse of white light causes FAD absorption to be red shifted in a biphasic process with a fast phase occurring in < 1 micros and a slow phase occurring at approximately 5 ms. The absorbance shift was spontaneously restored over a 30 min period, also in a biphasic process as assayed by fluorescence quenching and electronic absorption analyses. Site-directed replacement of Tyr21 with Leu or Phe abolished the photochemical reaction implicating involvement of Tyr21 in the photocycle. Nuclear magnetic resonance analysis of wild-type and mutant proteins also indicates that Tyr21 forms pi-pi stacking interactions with the isoalloxazine ring of FAD. We propose that photochemical excitation of the flavin results in strengthening of a hydrogen bond between the flavin and Tyr 21 leading to a stable local conformational change in AppA.

ABSTRACT: The fate of 14C-labeled sulfadiazine (SDZ) in manured soil has been investigated in laboratory test systems. In the first approach, stability of 14C-SDZ in liquid bovine manure has been tested. Only 1% of the initially applied radiotracer was mineralized to 14C-carbon dioxide and 82% were transferred to nonextractable residues within a 102-d incubation period. Test slurries with defined aged residues were prepared and, supplementary to standard solutions, applied to silty-clay soil samples. These tests showed the high affinity of 14C-SDZ residues to the soil matrix. In the second approach, basic data on microbial, chemical, and photoinduced degradability in soil were gathered. The data indicated the formation of nonextractable residues as the predominant process in soil, which was accelerated by the test slurry application. In the third approach, laboratory lysimeter tests were conducted to investigate leaching and degradation as simultaneously occurring processes. The 14C-SDZ residues (64%) mainly were retained in the surface layer as nonextractable residues. Although a high mobility in soil was revealed by a soil/water distribution coefficient of 2 L kg(-1), percolate contamination amounted to only 3% of the initially applied 14C-SDZ. The tendencies of leaching and degradability in soil also were observed in test plot studies under field conditions.

Document Type: Conference; Meeting Abstract; Computer Optical Disk
Language: written in English. Southern pine seed orchards are essential for establishment of pine forests. In 1998, 22,000 lb of seed was lost to coneworms and seedbugs in the South alone. Losses to insects of 50% are not uncommon. Azinephosmethyl and phosmet have been important in orchard IPM, but registration issues including worker exposure remained. This research sought a generic transfer coeff. (TC; cm2/h) for harvesters. Pyrethroid insecticides were advocated as replacement insecticides. Exposure, dislodgeable pine needle residues, and time worked were obtained. Needle residues were less than minimal reportable levels (.apprx. 0.05 mg/cm2) and became an unlikely source of harvester exposure. We biomonitored elimination of dimethyl- and dimethylthiophosphate AZM biomarkers in spot urine specimens of 13 harvesters from Texas and Louisiana who eliminated 0.1-5.3 mg AZM/kg bw-day (creatinine cor.). Unexposed controls were unavailable and low level biomarkers were probably contributed from diet and other environmental exposures. For regulatory purposes, follow-up studies will evaluate the low pesticide exposure potential of seed cone harvesting. [on SciFinder (R)]

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: PESTAB. A method is presented for the analysis of organophosphorus pesticides using capillary gas chromatography with flame photometric detection. A Tracor Model 550 instrument, equipped with a flame photometric detector, was modified for capillary column operation. The gas chromatographic conditions were: Pyrex, length 50 m, I.D. 0.35 mm; phase, SE-30 (GC grade). Restriction coil: stainless steel, length 1.40 m, I.D. 0.25 mm. Temperatures: oven, 200DEG and 240DEG ; detector, 210DEG . Gas flows: carrier gas (helium) 4 ml/min; splitting gas (helium) 24 ml/min; detector, hydrogen 200 ml/min, air 80 ml/min, oxygen 10 ml/min; purge gas (nitrogen) 60 ml/min. Injection: 1 mul of mixtures of the organophosphorus pesticides in acetone-light petroleum were injected through a septum on to the column. Retention times of pesticides relative to parathion are given for: trichlorfon, TEPP, naled, dichlorvos, mevinphos, heptenophos, zinophos, omethoate, prophos, bidrin, sulfotep, butonate, dimethoate, thiometon, AC 92.100, diazinon cyanthoate, dyfonate, disulfoton, formothion, dichlofenthion, parathion methyl, phosphamidon, prothoate, fenchlorphos, fenitrothion, pirimiphos methyl, malathion, dursban, parathion, bromophos, pirimithate, trichloronate, mecarbam, Bay 77049, chlorfenvinphos, fenthoate, ciodrin, supracide, vamidothion, Bay 77488, tetrachlorvinphos, bromophos ethyl, plondrel, triamyphos, ethion, triazophos, carbophenothion, menazon, imidan, phencapton, EPN, azinphos methyl, phosalone, azinphos ethyl, W 11099, dialifor, coumaphos, and abate. The detection limit for the phosphorus esters with a relative retention time of about 1 in the programmed mode is about 100 pg.

695. Kugler, M., Loeffler, W., Rapp, C., Kern, A., and Jung, G. (Rhizocticin a, an Antifungal Phosphono-Oligopeptide of Bacillus Subtilis Atcc 6633: Biological Properties. *Arch microbiol. 1990; 153(3):276-81. [Archives of microbiology]: Arch Microbiol.*
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

ABSTRACT: Rhizocticin A, the main component of the antifungal, hydrophilic phosphono-oligopeptides of Bacillus subtilis ATCC 6633, was used for sensitivity testing and experiments into the molecular mechanism of the antibiotic action. Budding and filamentous fungi as well as the cultivated nematode Caenorhabditis elegans were found to be sensitive, whereas bacteria and the protozoon Paramecium caudatum were insensitive. Rhizoctonia solani was inhibited in agar dilution tests but not in diffusion tests. The antifungal effect of rhizocticin A was neutralized by a variety of amino acids and oligopeptides. Oligopeptide influence was mainly understood as transport antagonism, and it was concluded that the antibiotic enters the recipient cell via the peptide transport system. L- and D-cystine were also identified as potent, general antagonists of the oligopeptide transport. The rhizocticin-antagonism of four other amino acids was taken as a clue to the site of action. Provided that rhizocticin A is split by peptidases of the target cell into inactive L-arginine and toxic L-2-amino-5-phosphono-3-cis-pentenoic acid (L-APPA), the latter may interfere with the threonine or threonine-related metabolism.

696. Kull', A. K. (Effects of Phthalophos in Chicken Embryos. *Veterinariya (moscow) 9: 104-106; 1975.*
Chem Codes: Chemical of Concern: PSM Rejection Code: NON-ENGLISH.

ABSTRACT: PESTAB. The embryotoxic and teratogenic action of phthalophos was studied in chicken embryos. Phthalophos in physiological solution was introduced into the amniotic cavity of 10 day-old embryos in doses of 6, 63, and 635 mg, or into the yolk sac of 7-8 day-old embryos in doses of 3, 317.5, or 635 mg. The overall mortality, indicating the embryotoxic effect of phthalophos, was 22.6-52.8%, and the incidence of teratogenic changes was 1.4-6.8%. The mortality rate was 15.6-45.7% after the introduction of physiological saline solution alone, and 15.6-45.7% spontaneous mortality was observed in the control group. The incidence of spontaneous teratogenic changes was 1.1-1.2% in the control group. The teratogenic effect of phthalophos was most pronounced on the mesodermal formations (extremities and abdominal wall), and weakest on the ectodermal formations, such as the brain, eyes, and bill.

ABSTRACT: A comparative study of the effect of 12 organophosphorus pesticides on mice was carried out. A statistically significant increase of the frequency of aberrant metaphases in bone-marrow cells of mice was induced by dipterex, metaphos, phosphamidon and imidan. No correlation between the toxicity and the mutagenic activity of the compounds studied was observed. The pesticides studied can be regarded as substances with a slight cytogenetic activity with respect to animals.

ABSTRACT: The cytogenetic action of three phosphoorganic pesticides, imidan, dipterex and gardona, in cultured human lymphocytes is studied. It is found that all the sunstances induce the signficant increase in the frequency of metaphases with chromosomes aberrations as compared with the control level. Maximal effects in vitro qere 6,0; 4,8 and 4,0% of aberrant cells for imidan, dipterex and gardona respectively. All investigated substances had a weak mutagenic activity in human lymphocyte culture.

ABSTRACT: PESTAB. The toxicity of phthalophos (phosmet) was studied in rabbits and chickens fed 50-600 mg/kg doses. The toxic effect of phthalophos manifested itself in functional disturbance of the sympathetic nervous system (miosis, bronchial spasm, sialorrhea, tremor, spasma, areflexia, diarrhea, asphyxia), dehydration, thickening of the blood, and extensive reduction of the acetylcholinesterase and Na,K-ATPase activities. The pathomorphological examination revealed hemodynamic, dystrophic and inflammatory-necrotic changes. The above symptoms as well as the determination of pthalophos in the gastric content and organs are pathognomonic.

ABSTRACT: PESTAB. The efficacy of antidote therapy was studied in Chinchilla rabbits and in hens poisoned with LD100 doses of phthalophos (160 mg/kg for rabbits, 600 mg/kg for hens), administered orally in aqueous suspension. The antidotes were administered i.m. immediately after the manifestation of the poisoning symptoms. The rabbits received tropacine and atropine (5 mg/kg each), dipyroxime (10 mg/kg), and isonitrosine (20 mg/kg, 1-5 times during the first day, then once daily). All untreated rabbits died in 20-60 min. The antidote therapy had 100% efficiency, the therapeutic effect manifested itself in 5-10 min. The hens received one to two doses of atropine (5 mg/kg), tropacine and dipyroxime (10 mg/kg each), and isonitrosine (20 mg/kg). The antidote therapy was ineffective in all hens; the untreated animals died 1-3 hr after poisoning, the treated ones 2-3 hr later.

ABSTRACT: PESTAB. Cytogenetic methods were employed for comparative evaluation of the mutagenic activity of 23 pesticides. Increased frequency of chromosome aberrations in bone marrow cells was recorded after administration to mice of high doses of tetramethylthiuramdisulfide (TMTD; thiram), ziram, Yalan (molinate), chlorophos (trichlorfon), phthalophos (phosmet), metaphos (methyl parathion), Valexon (phoxim), phosphamide (dimethoate) and 2,4-D. A number of derivatives of carbamic, thio-, and dithiocarbamic acids, urea derivatives, and hydrazine derivatives showed carcinogenic activity. Dithiocarbamate pesticides were found to pass across the placenta and cause embryotoxic and gonadotoxic effects. Teratogenic activity was recorded for derivatives of chlorophenoxyacetic acid.

ABSTRACT: Pesticide pollution of ground and surface water is of growing concern in tropical countries. The objective of this pilot study was to evaluate the leaching potential of eight pesticides in a Brazilian Oxisol. In a field experiment near Cuiabá, Mato Grosso, atrazine, chlorpyrifos, lambda-cyhalothrin, endosulfane alpha, metolachlor, monocrotofos, simazine, and trifluraline were applied onto a Typic Haplustox. Dissipation in the topsoil, mobility within the soil profile and leaching of pesticides were studied for a period of 28 days after application. The dissipation half-life of pesticides in the topsoil ranged from 0.9 to 14 d for trifluraline and metolachlor, respectively. Dissipation curves were described by exponential functions for polar pesticides (atrazine, metolachlor, monocrotofos, simazine) and bi-exponential ones for apolar substances (chlorpyrifos, lambda-cyhalothrin, endosulfane alpha, trifluraline). Atrazine, simazine and metolachlor were moderately leached beyond 15 cm soil depth, whereas all other compounds remained within the top 15 cm of the soil. In lysimeter percolates (at 35 cm soil depth), 0.8-2.0% of the applied amounts of atrazine, simazine, and metolachlor were measured within 28 days after application. Of the other compounds less than 0.03% of the applied amounts was detected in the soil water percolates. The relative contamination potentials of pesticides, according to the lysimeter study, were ranked as follows: metolachlor > atrazine = simazine >> monocrotofos > endsulfane alpha > chlorpyrifos > trifluraline > lambda-cyhalothrin. This order of the pesticides was also achieved by ranking them according to their effective sorption coefficient Ke, which is the ratio of Koc to field-dissipation half-life.

ABSTRACT: The potential of pesticides for nonpoint ground water pollution depends on their dissipation and leaching behavior in soils. We investigated the fate of 10 pesticides in two tropical soils of contrasting texture in the Brazilian Cerrado region near Cuiabá during an 80-d period, employing topsoil dissipation studies, soil core analyses, and lysimeter experiments. Dissipation of pesticides was rapid, with field half-lives ranging from 0.8 to 20 d in Ustox and 0.6 to 11.8 d in Psamments soils. Soil core analyses showed progressive leaching of polar pesticides in Psamments, whereas in Ustox pesticides were rapidly transported to 40 cm soil depth regardless of their sorption properties, suggesting that leaching was caused by preferential flow. In lysimeter experiments (35 cm soil depth), cumulative leaching was generally low, with < or = 0.02% and

< or = 0.19% of the applied amounts leached in Ustox and Psamments, respectively. In both soils, all pesticides but the pyrethroids were detected in percolate at 35 cm soil depth within the first 6 d after application. Cumulative efflux and mean concentrations of pesticides in percolate were dosely correlated with their Groundwater Ubiquity Score (GUS). The presence of alachlor (2-chloro-2', 6'-diethyl-N-methoxymethylacetanilide), atrazine (2-chloro-4-ethylamino-6-isopropylamino-1,3,5-triazine), metolachlor [2-chloro-N-(2-ethyl-6-methylphenyl)-N-(2-methoxy-1-methylethyl)acetamide], simazine [2-chloro-4,6-bis(ethylamino)-1,3,5-triazine], and trifluralin (2,6-dinitro-N,N-dipropyl-4-trifluoromethylaniline) throughout the soil profile and in percolate of wick lysimeters at 95 cm soil depth indicated that a nonpoint pollution of ground water resources in tropical Brazil cannot be ruled out for these substances.

ABSTRACT: The flavin adenine dinucleotide (FAD)-containing photoreceptor protein AppA (in which the FAD is bound to a novel so-called BLUF domain) from the purple nonsulfur bacterium Rhodobacter sphaeroides was previously shown to be photoactive by the formation of a slightly redshifted long-lived intermediate that is thought to be the signaling state. In this study, we provide further characterization of the primary photochemistry of this photoreceptor protein using UV-Vis and Fourier-transform infrared spectroscopy, pH measurements and site-directed mutagenesis. Available evidence indicates that the FAD chromophore of AppA may be protonated in the receptor state, and that it becomes exposed to solvent in the signaling state. Furthermore, experimental data lead to the suggestion that intramolecular proton transfer (that may involve [anionic] Tyr-17) forms the basis for the stabilization of the signaling state.

710. Labaw, L. W. and Rall, J. E. (1968). The crystal packing of thyroglobulin. *Journal of Molecular Biology* 36: 25-26.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The molecular packing in 19 s thyroglobulin crystals has been examined using shadowed, positively stained and negatively stained preparations. Crystallizing thyroglobulin molecules first form polymers which are right-handed helices with an average pitch of 228 A having four molecules per turn. The molecular shape appears to be approximately a sphere of 114 A diameter or a prolate ellipsoid of comparable volume. The three-dimensional packing of the helices can be described by an octamolecular orthorhombic unit cell having sides of 395, 228 and 197 A.

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: PESTAB. A screening method has been developed for determining organophosphorus pesticides at ng/l levels in drinking water. Sixteen organophosphorus pesticides, diazinon, diazinon-oxon, dimethoate, ronnel, beta-phosphamidon, methyl parathion, parathion, malathion, chlorpyrifos, fenitrothion, Reulene (crufomate), methidathion, ethion, EPN, phosphalone, and phosmet, were extracted by Amberlite XAD-2 resin from 100 and 200 l drinking water previously spiked with these pesticides. The pesticides were eluted from the XAD-2 resin with acetone-hexane (15+85). The concentrated extract was analyzed by gas chromatography using a nitrogen-phoshorus selective detector and by gas chromatography mass spectrometry using selection ion monitoring. Recoveries at the 10 and 100 ng/l spiking levels were greater than 90%, except recoveries for dimethoate and phosphamidon were 37 and 42%, respectively. The analysis of 300 l of Ottawa tap water showed no detectable amounts (< 1 ng/l) of any of the 16 organophbosphorus pesticides. (Author abstract by permission)

It involves a rapid extn. procedure and liq. chromatog. coupled to electrospray mass selective detection. Seven pesticides were extd. at pH 4.5 with a mixt. of acetone-dichloromethane-hexane (50:20:30, vol./vol./vol.). Ionization was performed at atm. pressure in an electrospray-type source and detection was carried out using the selected ion monitoring mode. Extn. recoveries were between 55 and 98% except for methylthiophanate (<20%). Limits of detection and limits of quantitation (LOQs) ranged, resp., from 0.01 to 0.02 mg/kg and from 0.02 to 0.05 mg/kg, with relative std. deviation (R.S.D.) <19%. An excellent linearity was obsd. for LOQs up to 5 mg/kg. Intermediate (\"inter-assay\") precision and accuracy were satisfactory. The method was applied to many fruit samples intended for commercialization. [on SciFinder (R)] 0021-9673 pesticide/ residue/ detection/ apple/ pear

The ionization was performed by electron Impact and acquisition in the single ion monitoring mode followed 3 specific ions per analyte. Extn. recoveries were satisfactory and ranged between 40 and 108% in blood and serum. Limits of detection ranged from 5 to 25 ng/mL and limits of quantitation (LOQs) ranged from 10 to 50 ng/mL, in blood and serum. An excellent linearity was obsd. from these LOQs up to 1000 ng/mL. Intra- and inter-assay precision and accuracy were satisfactory for most of the pesticides analyzed. [on SciFinder (R)] 0378-4347 organophosphorus/ pesticide/ GC/ MS/ blood/ analysis

These methods involved rapid solid-phase extn. using new polymeric support (HLB and MCX) OASIS cartridges. Gas chromatog.-mass spectrometry (GC-MS) was used for volatile (organophosphate, organochlorine, phthalimide, uracil) pesticides and liq. chromatog.-ionspray-mass spectrometry (LC-MS) for thermolabile and polar pesticides (carbamates, benzimidazoles). Acquisition was performed in the selected ion monitoring (SIM) mode. Extn. recovery varied owing to the nature of pesticides, but was satisfactory for all. Limits of detection (LODs) and limits of quantitation (LOQs) ranged, resp., from 2.5 to 20 and from 5 to 50 ng/mL. An excellent linearity was obsd. from LOQs up to 1000 ng/mL for all the pesticides studied. The proposed procedures yielded reproducible results with good inter-assay accuracy and precision. A few cases of intoxication are presented to demonstrate the diagnostic interest of these methods: in two cases were detd. lethal concns. of endosulfan and carbofuran; in four other cases, the procedures helped diagnose intoxication with, resp., parathion-Et, the assocn. of bromacil and strychnine, bifenthrin and aldicarb. ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Gas chromatography with nitrogen-phosphorus detection (GC-NPD) using three different capillary columns, DB-1701, RSL-300 and DB-5, was employed for the identification of 25 organophosphorus pesticides and various transformation products. Spectral information on and typical fragment ions of the different compounds were obtained by gas chromatography-mass spectrometry with electron impact and negative-ion chemical ionization. Clean-up methods involving Florisil, Empore C18 extraction discs, C18 cartridges and gel permeation chromatography using Bio-Beads S-X3 were evaluated for the isolation of selected organophosphorus pesticides from water and biota samples. Recoveries for water samples varied from 77 to 120% with a relative standard deviation of 2-8% whereas recoveries of 30-130% were obtained with biota samples. Applications are reported for the determination of pyridafenthion in water samples from the Ebro delta (Tarragona, Spain).

Several different storage conditions were tested, which included storage at 4 Deg and -20 Deg, and a combination of 2 conditions where precolumns were stored at 4 Deg for 1.5 mo and held at room temp. until anal. (0.5 and 1 mo). Complete recovery was obsd. in precolumns kept in at -20 Deg for 8 mo except for mevinophos, dichlorvos, and phosmet, which had recoveries of 22-58%. Degrdn. also occurred for these same OP pesticides when precolumns were stored at 4 Deg for 2 mo and at room temp. for 1 mo, with losses varying 21-78% and 41-61%, resp. Complete degrdn. of fenamiphos and fonofos occurred in precolumns stored at 4 Deg and at room temp. The stability of the pesticides in each storing treatment is related to the hydrolytic processes and their soly. in water. Spectral information on and typical fragment ions of the different compds. were obtained by gas chromatog.-mass spectrometry with electron impact and neg.-ion chem. ionization. Clean-up methods involving Florisil, Empore C18 extn. disks, C18 cartridges, and gel permeation chromatog. using Bio-Beads S-X3 were evaluated for isolation of selected organophosphorus pesticides from water and biota samples. Recoveries for water samples was 77-120% with a relative std. deviation of 2-8%, whereas recoveries of 30-130% were obtained with biota samples. Applications are reported to det. pyridafenthion in water samples from the Ebro delta (Tarragona, Spain). [on SciFinder (R)] 0003-2670 screening/ organophosphorus/ pesticide/ water

718. Laframboise, J. G. and Chang, Jen-Shih (1977). Theory of charge deposition on charged aerosol particles of arbitrary shape. *Journal of Aerosol Science* 8: 331-338.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The theory of charge collection by a charged equipotential aerosol particle in a stationary medium having no external electric fields, is re-examined for arbitrary particle shape. In the continuum limit, when the particle size is much greater than the ion mean free path, we show that the expression for charging current dependence on particle surface potential, previously derived for spheres by Fuchs and others, has the same form for all particle shapes. In the general (finite mean-free-path) case, we obtain an approximate charging current expression which we evaluate in detail for oblate and prolate spheroids. This result is shown to have the correct form in the collisionless (large mean-free-path) limit if the particle surface potential is repelling for the ion species considered. This leads to a prediction that for a very elongated spheroid, charged collection will be much more sensitive to departure from collisionless conditions than in the case of a sphere of the same equatorial radius. http://www.sciencedirect.com/science/article/B6V6B-48C78CN-2P/2/93aab36d0952b1ab32f916f26d8db009

CAS Registry Numbers: 55-38-9 (Fenthion); 56-38-2 (Parathion-ethyl); 56-72-4 (Coumaphos); 86-50-0 (Azinphos-methyl); 121-75-5 (Malathion); 122-14-5 (Fenitrothion); 298-00-0 (Parathion-methyl); 298-02-2 (Phorate); 298-04-4 (Disulfoton); 299-84-3; 311-45-5 (Paraoxon-ethyl); 333-41-5 (Diazinon); 470-90-6; 732-11-6 (Phosmet); 786-19-6 (Carbofenothion); 944-22-9 (Fonofos); 950-35-6 (Paraoxon-methyl); 950-37-8 (Methidathion); 1634-78-2 (Malaoxon); 2310-17-0 (Phosalone); 2642-71-9 (Azinphos-ethyl); 2921-88-2 (Chlorpyriphos); 3383-96-8 (Temephos); 5598-13-0; 13593-03-8 (Quinalphos); 14816-18-3 (Phoxim); 23505-41-1 (Pirimiphos-ethyl); 24017-47-8 (Triazophos); 25311-71-1 (Isofenphos); 29232-93-7 (Pirimiphos-methyl); 38260-54-7 (Etrimfos) Role: ANT (Analyte), POL (Pollutant), ANST (Analytical study), OCCU (Occurrence) (organophosphorus pesticides and metabolites in crops detd. by solid-phase extn. followed by liq. chromatog./diode array detection); 67-56-1 (Methanol); 75-05-8 (Acetonitrile) Role: ARU (Analytical role, unclassified), ANST (Analytical study) (organophosphorus pesticides and metabolites in crops detd. by solid-phase extn. followed by liq. chromatog./diode array detection, mobile phase) A multiresidue method for the anal. of 28 common organophosphorus pesticides and 3 of their main metabolites (paraoxon-Et, paraoxon-Me, and malaoxon) in crop was developed. An aliquot of the chopped sample is homogenized with an org. solvent. The efficiency of extn. methods using MeOH, acetone, and acetonitrile was evaluated. Acetonitrile gives higher recoveries and minimizes co-extractives from the samples matrix. The resulting aq. acetonitrile ext. is filtered and cleaned by solid phase extn. (SPE). For SPE 3 different types of adsorption materials (Carbograph 1, LiChrolut-EN, and Amberchrom CG-161m) were compared. The cleaned-up ext. is injected into the LC system. Three different anal. columns were tested in conjunction with 2 mobile phase compns. of different polarity. The use of LC-DAD techniques allowed the identification of both organophosphorus pesticides and metabolites by means of std. and spectral comparison, resp. The accuracy of the quant. detn. measured in terms of av. percentage recovery of 31 compds. in crop samples was 61-96% with a relative std. deviation of 5-10%. I (Markush included), N-oxides or an agriculturally suitable salts thereof are prepd. as insecticides for controlling lepidopteran, homopteran, hemipteran, thysanopteran and coleopteran insect pests. Insecticidal compn. contg. anthranilamide compds. I may further comprise addnl. biol. active compds. selected from arthropodicides of the group consisting of pyrethroids, carbamates, neonicotinoids, neuronal sodium channel blockers, insecticidal macrocyclic lactones, g-aminobutyric acid (GABA) antagonists, insecticidal ureas, and juvenile hormone mimics. Patent Application Country: Application: WO
Priority Application Country: US
Priority Application Number: 2000-254636
Priority Application Date: 20001211 The title compds. [I; J = (un)substituted pyrazolyl, pyridyl, pyrimidyl, etc.; R1 = H, alkyl, alkoxycarbonyl, alkylcarbonyl; R2 = H, alkyl; R3 = H, alkyl, alkenyl, etc.; one R4 is attached to the Ph ring at the 3-position or 6-position, and said R4 = alkyl, haloalkyl, halo, etc.; an optional second R4 = H, alkyl, cycloalkyl, etc.; n = 1-2], useful for controlling invertebrate pests, were prepd. E.g., a multi-step synthesis of 3-iodo-II [R3 = iso-Pr; R4 = 3-I; R7 = OCH2CF3; X = CH; Y = CH; Z = N] and 6-iodo-II [R3 = iso-Pr; R4 = 6-I; R7 = OCH2CF3; X = CH; Y = CH; Z = N], was given. Both compds., 3-iodo-II and 6-iodo-II , were evaluated for control of diamondback moth in a container with radish plant, and both provided excellent levels of plant protection (10% or less feeding damage). Also disclosed are compns. for controlling an invertebrate pest comprising a biol. effective amt. of a compd. I and methods for controlling an invertebrate pest comprising contacting the invertebrate pest or its environment with a biol. effective amt. of a compd. I (e.g., as a compn. described herein). Chem Codes: Chemical of Concern: PSM Rejection Code: MODELING.

The molecular weight of lobster arginine kinase has been found to be 42 000 using high speed sedimentation equilibrium. Various experimental constants related to hydrodynamic behaviour have been determined and used to obtain an estimation of the shape of the hydrodynamic particle. This behaves like a globular unit equivalent to a prolate ellipsoid with an axial ratio of 3-4:1.

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: Field studies monitoring herbicide pollution in the vineyards of Burgundy (France) have revealed that drinking water reservoirs are contaminated with several pre-emergence herbicides. An assessment of the leaching of two such herbicides, diuron and oryzalin, was therefore performed using lysimeters, under outdoor conditions, from May 2001 to May 2002. Four vineyard soils from Vosne-Romanée (Burgundy) were chosen along a topolithosequence: a rendosol and three calcosols. After 673 mm of rainfall, greater amounts of diuron than oryzalin were measured in percolates: respectively 0.10-0.84% and 0.02-0.43% of applied herbicide, depending on soils. Measurements for diuron metabolites detected greater amounts of DCPMU than DCPU in the percolates: respectively 0.05-0.13% and 0-0.04% of the applied diuron. At the end of the monitoring period, more residues of diuron than oryzalin were recovered in the soil profiles: respectively 4.6-9% and 1.4-4.4%. The oryzalin residues were found mainly in the upper 10 cm of soil columns, whereas diuron residues were present in the whole core. The mobility of both oryzalin and diuron seems fairly well-related to soil organic carbon content; the mobility of diuron is also related to soil texture (sand and coarse material contents). Under such experimental conditions, this study confirms that diuron leaching, and therefore potential groundwater contamination, is greater than that of oryzalin.

729. Landry, E. F., Vaughn, J. M., Thomas, M. Z., and Beckwith, C. A. (Adsorption of Enteroviruses to Soil Cores and Their Subsequent Elution by Artificial Rainwater. *Appl environ microbiol. 1979, oct; 38(4):680-7. [Applied and environmental microbiology]: Appl Environ Microbiol*.
Chem Codes: Chemical of Concern: PSM Rejection Code: VIRUS.

ABSTRACT: The adsorption and elution of a variety of human enteroviruses in a highly permeable, sandy soil was studied by using cores (43 by 125 mm) collected from an operating recharge basin on Long Island. Viruses studied included field and reference strains of polioviruses types 1 and 3 and reference strains of coxsackie virus B3 and echovirus types 1 and 6. Viruses

suspended in treated sewage effluent were allowed to percolate through soil cores, and the filtrate was assayed for unadsorbed viruses. To determine the likelihood of desorption and mobilization, soil-bound viruses were subjected to a rinse with either treated sewage effluent or simulated rainwater which reflected the anion, cation, and pH characteristics of a typical northeastern United States rainfall. The results demonstrated that all polioviruses tested, including both reference and field strains, adsorbed extremely well to cores. Adsorption was somewhat reduced when clean, unconditioned soils were used. Soil-bound poliovirus strain LSc was not significantly mobilized by flooding columns with either a sewage effluent or rainwater rinse. One virus was mobilized by both types of rinses. The amount of viruses mobilized by rainwater rinses ranged from 24 to 66%. Variable adsorption-elution results were observed with other enteroviruses. Two guanidine-resistant mutants of poliovirus LSc demonstrated a soil adsorption-elution profile different from that of the parent strain. The data support the conclusion that soil adsorption-elution behavior is strain dependent and that poliovirus, particularly strain LSc, represents an inappropriate model.

730. Langenakens, Jan J., Vandewalle, Xavier, and De Baerdemaeker, Josse (1997). Influence of Global Shape and Internal Structure of Tomatoes on the Resonant Frequency. *Journal of Agricultural Engineering Research* 66: 41-49.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The firmness of a tomato can be estimated non-destructively from the measurement of its resonant frequency. The purpose of this research was to investigate the reliability of this technique in relation to the global shape and the internal structure of a tomato. The dynamic behaviour of spherical and non-spherical tomatoes was studied first by experimental modal analysis. Mode shapes, excitation techniques and measurement points for obtaining high impulse responses are compared. The effect of the internal compartmental structure of a tomato on the responses at different excitation points was studied. From the measured frequency response functions, the second resonant frequency, with an "oblate-prolate " synchronized motion of the fruit, was selected for further use. The corresponding mode shape incorporates the largest deformations for the small impact excitation used. The best repetitive results with greatest discrimination from other modes are obtained by impacting and measuring the response at the equator, at points 180[degree sign] from each other, for both spherical and non-spherical tomatoes. Impacting and or measuring the tomato on fleshy or juicy parts of the tomato resulted in a small change (less than 0[middle dot]5%) in the resonant frequency. During ripening, on the other hand, the resonant frequencies of all mode shapes decreased gradually. A testing procedure based on measurements of the resonant frequencies, namely the acoustic impulse response technique, is proposed.

731. Langenbach, T., Schroll, R., and Scheunert, I. (Fate of the Herbicide 14c-Terbuthylazine in Brazilian Soils Under Various Climatic Conditions. *Chemosphere. 2001, oct; 45(3):387-98. [Chemosphere]: Chemosphere.*

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: 14C-terbuthylazine was applied to three Brazilian soils in closed aerated laboratory microcosms, both under standardized and under natural Brazilian climate conditions. Volatilization from soil to air, leaching from soil to percolate water, and transport from upper to deeper soil layers were higher in sandy soil than in clay soil and in organic soil. Mineralization of 14C-terbuthylazine to 14CO2 was higher in sandy soil than in clay and organic soils under standardized climatic conditions, whereas it was higher in organic soil than in sandy soil under Brazilian summer conditions. Under natural Brazilian summer conditions, leaching as well as vertical transport within the soil were enhanced as compared to standardized climate conditions comprising lower precipitation rates; volatilization was strongly reduced under high irrigation conditions.

Role: PEP (Physical, engineering or chemical process), POL (Pollutant), OCCU (Occurrence), PROC (Process) (degrdn. kinetics of organophosphorus and organonitrogen pesticides in water)
The evolution of a mixt. contg. 19 organophosphorus (OP) and organonitrogen (ON) pesticides at ppb level was studied over a 6-mo period in different water types (ultrapure water, natural seawater, river water, filtered river water) and under various conditions. The degrdn. kinetics were monitored in closed bottles in darkness at two temps. (6 and 22 Deg) and in a system exposed to natural sunlight (variable temp.). The mixt. was analyzed by gas chromatog. coupled with a nitrogen phosphorus detector (GC/NPD). Energy activation (Ea) and half-lifetimes (t1/2) were detd. Very different degrdn. behavior with respect to physicochem. conditions and mol. structures of the pesticides was obsd. These expts. confirm that half-lives of OP pesticides can be more than several months and consequently lead to lasting environmental pollution. 740. Laughrea, Michael and Moore, P. B. (1977). Physical properties of ribosomal protein S1 and its interaction with the 30 S ribosomal subunit of Escherichia coli. *Journal of Molecular Biology* 112: 399-421.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

Ribosomal protein S1 behaves in solution like a 10:1 prolate ellipsoid. Its tertiary structure is stabilized by considerable [beta]-sheet and little [alpha]-helix (~10% [alpha]-helix, ~40% [beta]-sheet). S1 bound to 30 S subunit is freely exchanged both with S1 free in solution and between subunits. Activated 30 S subunits (Zamir et al., 1971) bind one equivalent of S1 per particle; unactivated preparations can bind two. http://www.sciencedirect.com/science/article/B6WK7-4M34SDY-3/2/73107c11cf6e1843c0dc57549ef5de54

ABSTRACT: Sponsored by Department of Energy, Washington, DC.
ABSTRACT: As part of a safety analysis of reactions in two-layer mixtures of nitric acid and tributyl phosphate (TBP), an experiment was conducted to study how steam condensate mixes with the TBP layer when steam passes over a TBP-nitric acid mixture. The experiments showed that the condensate does not form a separate layer on top of the TBP but instead percolates as droplets through the TBP layer. The temperature at the top surface of the TBP layer undergoes a step change increase when the initial condensate droplets reach the surface. Temperatures at the surface and within the TBP and aqueous layers subsequently approach a steady state distribution governed by laminar convection and radiation heat transfer from the vapor space above the two-layer mixture. The rate of temperature increase and the steady state temperature gradient are determined by a characteristic propagation velocity and a streamwise dispersion coefficient for heat transfer. The propagation velocity is the geometric mean of the thermal convection velocities for the organic and aqueous phases, and the dispersion coefficient equals 0.494 times the product of the superficial condensate droplet velocity and the diameter of the test vessel. The value of the dispersion coefficient agrees with the Joshi (1980) correlation for liquid phase backmixing in bubble columns. Transient perturbations occur in the TBP layer temperatures. A Fourier analysis shows that the dominant frequency of these perturbations equals the natural frequency given by the transient heat transfer solution.

Patent Application Country: Application: US
Priority Application Country: US
Priority Application Number: 2003-461547
Priority Application Date: 20030409 The wood preservative compns. comprising micronized particles. The compn. comprises dispersions of micronized metal or metal compds. The wood preservative compn. comprises an inorg. component comprising a metal or metal compd. and org. biocide. When the compn. comprises an inorg. component and an org. biocide, the inorg. component or the org. biocide or both are present as micronized particles. When used for preservation of wood, the micronized particles can be obsd. as uniformly distributed within the wood and there is minimal leaching of the metal and biocide from the wood. ABSTRACT: We describe a sensitive and specific high-performance liquid-chromatographic method for determining the benzene metabolite, trans,trans-muconic acid (ttMA) in urine by measuring ultraviolet absorbance at 265 nm. We mix 1 mL of urine sample with 2 mL of Tris buffer containing vanillic acid as internal standard (IS) and percolate this through a preconditioned ion-exchange column. After rinsing the column with phosphoric acid solution, acetate buffer, and deionized water, we elute the analytes with 2 mL of an equivolume solution of 1.5 mol/L sodium chloride and methanol. Of this, 5 microL is injected into the HPLC column. The mobile phase used consists of, per liter, 10 mL of acetic acid, 100 mL of methanol, and the rest 5 mmol/L sodium acetate. The flow rate was started at 1 mL/min and increased to 1.5 mL/min after 6 min. ttMA and IS were detected at 5.2 and 10.2 min, respectively. The lowest detection limit is 125 pg. Analytical recovery and reproducibility generally exceeded 90%. We validated the method with urine samples collected from normal persons and from refinery workers exposed to benzene concentrations < 1 microL/L. The results show that urinary ttMA is a promising biological marker for risk assessment of low-concentration benzene exposure.

The resulting aq. acetonitrile ext. is filtered and cleaned up via reverse-phase solid extn. app. The pH of the filtrate is adjusted to neutral using phosphate buffer and the acetonitrile layer is sepd. from the aq. layer by a salting out process. An aliquot of the acetonitrile layer is concd. with a K-D evaporator by forming an azeotrope with n-hexane. The prepd. sample is assayed for pesticide residues using GLC and HPLC. The performance of this method was evaluated by fortifying 6 representative fruits and vegetables with 7 chlorinated hydrocarbons. 7 Organophosphate and 7 N-methylcarbamate pesticides at 0.1-0.2 ppm. No matrix interference was obsd. and the recovery of residues varied among different samples as well as different pesticides. Chlorothalonil results varied widely with irreproducible recoveries. In general, the method appears to be fast, rugged, and able to detect routinely at the 0.01 ppm level. The acute toxicity of these pesticides is governed by the irreversible inhibition of the enzyme acetylcholinesterase (AChE), after their metabolic activation to oxon analogs. The model is based on the idea that, for chems. exhibiting an irreversible receptor interaction, mortality is assocd. with a crit. amt. of \"covalently occupied\" target sites, i.e., the \"crit. target occupation\" (CTO). For a given compd. and species, this CTO is assocd. with a crit. time-integrated concn. of the oxon analog in the target tissue, which can be modeled by the crit. area under the curve (CAUC) that describes the time-concn. course of the phosphorothionate in the aq. phase or in the entire aquatic organism. In contrast to the classical crit. body residue (CBR) model, the CTO model successfully describes the 1-14-d LC50(t) data of several phosphorothionates in the pond snail and guppy. Furthermore, the time dependency of lethal body burdens (LBBs) of phosphorothionates is explained by the model. Although the CTO model is specifically derived for OP pesticides, it can be applied to analyze the acute toxicity and to est. incipient LC50 values of org. chems. that exert an irreversible receptor interaction in general. Chem Codes: Chemical of Concern: PSM Rejection Code: FATE, CHEM METHODS.

Limited proteolysis of cellobiose dehydrogenase (CDH) from the white rot fungus Phanerochaete chrysosporium by papain cleaves the enzyme into two fragments containing flavin (FAD) and heme, respectively. Small-angle X-ray scattering (SAXS) was employed to investigate size and shape of intact CDH and of its fragments in solution. The largest dimension of CDH amounts to about 18 nm, whereas the corresponding quantity of each of the two fragments is only around 9 nm. CDH as well as its fragments appear to be of prolate shape, the cross-section of the FAD fragment (diameter 4.3 to 5.1 nm) being considerably larger than that of the heme fragment (diameter 3.3 nm). These findings suggest a collinear arrangement of the two domains in the CDH particle. Simulations based on the method of finite elements corroborate this structure model and furthermore suggest the existence of a possibly flexible linker between the two domains

Chem Codes: Chemical of Concern: PSM Rejection Code: SURVEY.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Little is known of the impact of agricultural activity on oysters in Chesapeake Bay tributaries. As a preliminary assessment of pesticide residues in oyster tissues, this study monitored more than 60 pesticides in oysters and overlying water in two tributaries of the Chesapeake Bay. Paired water and oyster samples were collected throughout 1997 from the Patuxent and Choptank Rivers which discharge into opposite shores of the Chesapeake Bay in Maryland. In water, herbicides such as atrazine, simazine, cyanazine, and metolachlor were present throughout the year with individual water concentrations peaking as high as 430 ng/l in the late spring and summer and subsiding in the fall. These herbicides were not detected in the oysters even when concentrations were highest in the water. Another herbicide, trifluralin, was detected throughout the year at concentrations of less than 0.6 ng/l and 0.4 ng/g (wet weight) in water and oyster samples, respectively. Several insecticides

754. Lehotay, S. J. and Lee, C. H. (1997). Evaluation of a Fibrous Cellulose Drying Agent in Supercritical Fluid Extraction and Pressurized Liquid Extraction of Diverse Pesticides. *Journal of chromatography a* 785: 313-327.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. A fibrous cellulose powder (CF-1) was investigated as a drying agent for supercritical fluid extraction (SFE) and pressurized liquid extraction (PLE), also known as accelerated solvent extraction. Analysis of fifty-eight diverse pesticides was performed using gas chromatography-ion-trap mass spectrometric detection (GC-ITD). Extraction efficiencies were correlated versus pesticide polarity with samples of different water-CF-1 ratios. The effect of water was much more pronounced in SFE using CO_2 than PLE using acetonitrile, Pesticide recoveries and limits of detection of fortified tomato samples mixed with CF-1 were determined. PLE gave recoveries $> 80\%$ for nearly all pesticides, and SFE gave similar recoveries except for the most polar and non-polar pesticides. SFE typically gave lower detection limits than PLE due to fewer matrix interferants.

(SFE) of fruits and vegetables poses unique sample prepn. considerations because the sample size is small (1-3 g) and the analyte is distributed in a moist solid matrix. The goal of this research was to develop practical sample prepn. procedures for SFE of pesticide residues in produce so that acceptable accuracy and precision are maintained. In this study, 130 extns. of potato, fortified with up to 40 pesticides, were performed with 2 com. SFE instruments. Exts. were analyzed by gas chromatog. with ion trap mass spectrometry or electron capture detection. Four sample prepn. procedures were tested and Hydromatrix was used to control the amt. of water in the sample. The highest recoveries and lowest std. deviations were obtained when 20-50 g samples were blended with an equal amt. of Hydromatrix and dry ice was added to keep the samples frozen. The dry ice helped produce a homogeneous flowable powder and greatly reduced the degrdn. or vaporization of several pesticides. Recoveries of most pesticides from subsamples of <4 g with this procedure were 90-105%, with relative std. deviations of 1-6%. Only diphenylamine and disulfoton gave reduced recoveries with this procedure. When samples were extd. sequentially with an autosampler, certain pesticides were degraded in the extn. vessels over a period of several hours. To avoid losses of these pesticides, the sample in the extn. vessel was either purged with CO_2 to remove oxygen or kept frozen until extd. Peach and orange check samples were analyzed with the method, and results were comparable with those from traditional analyses. [on SciFinder (R)]

Citations: 35) Lehotay, S; J AOAC Int 2005, 88, 630 Validation expts. were conducted of a simple, fast, and inexpensive method for the detn. of 229 pesticides fortified at 10-100 ng/g in lettuce and orange matrixes. The method is known as the quick, easy, cheap, effective, rugged, and safe (QuEChERS) method for pesticide residues in foods. The procedure involved the extn. of a 15 g sample with 15 mL acetonitrile, followed by a liq.-liq. partitioning step performed by adding 6 g anhyd. MgSO4 plus 1.5 g NaCl. After centrifugation, the ext. was decanted into a tube contg. 300 mg primary secondary amine (PSA) sorbent plus 1.8 g anhyd. MgSO4, which constituted a cleanup procedure called dispersive solid-phase extn. (dispersive SPE). After a second shaking and centrifugation step, the acetonitrile ext. was transferred to autosampler vials for concurrent anal. by gas chromatog./mass spectrometry with an ion trap instrument and liq. chromatog./tandem mass spectrometry with a triple quadrupole instrument using electrospray ionization. Each anal. method was designed to analyze 144 pesticides, with 59 targeted by both instruments. Recoveries for all but 11 of the analytes in at least one of the matrixes were between 70-120% (90-110% for 206 pesticides), and repeatabilities typically <10% were achieved for a wide range of fortified pesticides, including methamidophos, spinosad, imidacloprid, and imazalil. Dispersive SPE with PSA retained carboxylic acids (e.g., daminozide), and <50% recoveries were obtained for asulam, pyridate, dicofol, thiram, and chlorothalonil. Many actual samples and proficiency test samples were analyzed by the method, and the results compared favorably with those from traditional methods. (SFE) and gas chromatog./ion trap mass spectrometry (GC/ITMS) was developed for anal. of 46 pesticides in fruits and vegetables. The SFE procedure used 2 com. instruments that trapped the exts. on solid-phase material. Silica gel chem. bound to octadecylsilane (ODS) collected the extd. pesticides efficiently, and elution of the trap with acetonitrile gave high recoveries. Exts. thus obtained were sufficiently clean for subsequent GC/ITMS anal. The SFE conditions were 320 atom and 60 DegC (0.85 g/mL CO2 d.) and 1.6 mL/min CO2 flow rate for 6 extn. vessel vols. Trapping on 1 mL ODS occurred at 10 DegC, and a 0.4 mL/min flow rate of acetonitrile at 40 Deg-50 DegC was used to elute the pesticides. Quant. and qual. analyses of the 46 pesticides were performed simultaneously by GC/ITMS. Studies of fortified samples gave >80% recoveries for 39 pesticides, and recoveries of >50% for the other pesticides, except methamidophos and omethoate. Grapes, carrots, potatoes, and broccoli were used as samples during method development, and a blind expt. involving incurred and fortified samples was used to test the approach. Results of the blind study compared satisfactorily with results from 7 labs. using traditional GC detectors and solvent-based extns. (GC) for semivolatile analytes such as pesticides. DSI of complex samples such as eggs requires a very selective detection technique, such as tandem mass spectrometry (MS-MS), to det. the analytes among the many semivolatile matrix components that also appear. In DSI, the nonvolatile matrix components that normally would contaminate the GC system in traditional injection methods remain in a disposable microvial, which is removed after every injection. For example, 3 mg of nonvolatile residue typically remained in the microvial after an injection of egg

ext. using the DSI method. This anal. procedure involves the following: (i) weighing 10 g of egg in a centrifuge tube and adding 2 g of NaCl and 19.3 mL of acetonitrile (MeCN); (ii) blending for 1 min using a probe blender; (iii) centrifuging for 10 min; and (iv) analyzing 10 mL (5 mg of egg equiv.) of the ext. using DSI/GC/MS-MS. No sample cleanup or solvent evapn. steps were required to achieve quant. and confirmatory results with <10 ng/g detection limits for 25 of 43 tested pesticides from several chem. classes. The remaining pesticides gave higher detection limits due to poor fragmentation characteristics in electron impact ionization and/or degrdn. Anal. of eggs incurred with chlorpyrifos-Me showed a similar trend in the results as a more traditional approach. [on SciFinder (R)] 0021-8561 food/ analysis/ egg/ pesticide/ GC/ MS

(SFE), elution of analytes, and clean-up of orange, sweet potato and green bean exts. for anal. of 56 diverse pesticides using GC-ion-trap MS. The solid-phase traps evaluated consisted of octyldecylsilane (ODS), diol, Tenax and Porapak-Q, and the elution solvents compared were acetone, Et acetate, acetonitrile and methanol. SFE collection by bubbling into each org. solvent was also compared. Recoveries, elution vols., limits of detection and clean-up aspects were detd. for each combination of commodity, trap and solvent tested. High trapping efficiencies were achieved in each case, and acetone usually eluted the pesticides in the least vol. (<1 mL) from the traps. The few matrix components that interfered in GC-ion-trap MS continued to interfere in all trap/solvent pairs, and limits of detection were independent of trap/solvent combination. The use of the ODS trap and acetone elution solvent gave the most consistently high recoveries of the traps and solvents tested. 760. Leibfried, R. T. (Chemical Interactions Between Forest Soils and Acidic Precipitation During a Dormant Season on Wildcat Run Watershed in Southwestern Pennsylvania. *Govt reports announcements & index (gra&i), issue 07, 1983*.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: TD3: In order to assess the chemical interactions between forest soil and acidic precipitation, water samples were collected at the soil surface and beneath organic and mineral soil horizons on Wildcat Run Watershed in southwestern Pennsylvania during the 1980-81 dormant season. Leachate samples were collected from the three major soil series on the watershed using zero-tension pan lysimeters to determine chemical changes produced by the different soil horizons. Mean pH was 4.0, 3.9, and 4.4 for surface snowmelt and rain, organic soil leachate, and mineral soil leachate, respectively; indicating a significant retention of H(+) in -1 the mineral soil horizons. Mean aluminum concentration was 0.44, 1.03, and 3.59 mg.l at the same three collection depths. Collection depth was the most important factor affecting percolate chemistry while soil series, size-of-event, and precipitation-type were of lesser importance. Master's thesis,

Citations: Podhorniak, L; J AOAC Int 2001, 84, 873 A two-year study was initiated in 2002 to profile the fate of eighteen pesticide residues through a com. peach canning process. Of the 18 pesticides, ten were parent compds. and the remaining eight compds. were metabolites that the United States Environmental Protection Agency (U.S. EPA) identified as potential environmental or human concerns. The pesticides examd. were azinphos-Me, azinphos-Me oxygen analog, phosmet, phosmet oxygen analog, chlorpyrifos, chlorpyrifos oxygen analog, propiconazole, fenbuconazole, RH-129, RH-130, triazole acetic acid (TAA), triazole alanine (TA), 1,2,4 triazole, captan, chlorothalonil, permethrin, esfenvalerate, and oxytetracycline (OTC). In 2002 and 2003, fruit samples of three late ripening peach cultivars ('Ouachita Gold', 'Encore', and 'Faye Elberta') were collected from three com. growers. Four different sample points were taken through the canning process: the whole peach, half of the peach with the peel, half of the peach without the peel, and the canned peach. There was a significant difference ($P = 0.05$) in residue concns. (ppb) of the parent compds. between the whole peach, the half peach with peel, and the half peach without the peel samples. However, there were no significant difference in residue concns. found between the half peach without the peel and the canned peach samples. The dissipation rate of metabolite residues varied from compd. to compd. The residues from organophosphate metabolites followed the same dissipation trend as the parent compds. However, the triazole metabolites TA and TAA dissipated much slower through the canning process, while 1,2,4 triazole was not detected in any of the samples. All samples analyzed in this study were below the U.S. EPA tolerances. [on SciFinder (R)] 0567-7572 pesticide/ peach/ canning

Abstract: (bullet) Background and Aims: Marcgraviaceae are a rather small family of seven genera and approx. 130 neotropical species. This study aims to present a detailed palynological survey of the family in order to comment on the intrafamily relationships and possible correlations with pollinators. (bullet) Methods: In total, 119 specimens representing 67 species and all genera are observed using light microscopy and scanning electron microscopy. Furthermore, eight species from five genera are studied with transmission electron microscopy. (bullet) Key Results: Our results show that pollen grains of Marcgraviaceae are small (20-35 (mu)m), have three equatorial apertures, granules on the colpus membrane, oblate spheroidal to prolate spheroidal shapes, mainly psilate to perforate ornamentations, and lalongate colpus-shaped thinnings at the inner layer of the exine, and show the presence of orbicules. Based on our fragmentary knowledge of the pollination biology of the family, there are no clear correlations between pollinators and pollen features. (bullet) Conclusions: The genus Marcgravia has a high percentage of reticulate sexine patterns and a relatively thin nexine. Sarcopera can be defined by the presence of an oblate spheroidal to even suboblate shape, while Ruyschia and Souroubea typically show prolate spheroidal to subprolate pollen grains. The presence of a thick foot layer in the pollen wall is characteristic of the genera Norantea, Sarcopera and Schwartzia. Pollen features that are taxonomically useful within the family are the shape, sexine sculpturing, and ultrastructure of the pollen wall.

763. Leonard, K. R., Kleinschmidt, A. K., Agabian-Keshishian, Nina, Shapiro, Lucille, and Maizel, J. V. (1972). Structural studies on the capsid of Caulobacter crescentus bacteriophage [phi]CbK. *Journal of Molecular Biology* 71: 201-204.
Chem Codes: Chemical of Concern: PSM Rejection Code: VIRUS.

Electron microscopy, combined with optical diffraction, has been used to investigate the topological structure of the head or capsid of Caulobacter crescentus bacteriophage [phi]CbK. Analysis of optical diffraction patterns from micrographs of negatively stained and metal-shadowed phage heads has enabled a model to be constructed for the non-isometric capsid. The model consists of a prolate cylindrical surface lattice with 5-fold rotational symmetry closed at each end by a pentagonal pyramidal cap. Optical filtering and image reconstruction gave additional information on the distribution of protein in the surface of the [phi]CbK capsid. The protein composition of the phage has been determined by gel electro-phoresis, the results indicating that three major proteins make up the capsid. The relation between the numerical distribution of these proteins and the proposed model for the capsid is discussed.

764. Leong, K. H. (1984). Thermophoresis and diffusiophoresis of large aerosol particles of different shapes. *Journal of Aerosol Science* 15: 511-517.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The thermophoresis and diffusiophoresis of nonspherical aerosol particles is examined. The representative particle shapes studied are cylinders and oblate and prolate spheroids. Phoretic velocities are derived for these particles of different shapes for the case of large particles in the slip regime of flow. Results indicate that diffusiophoresis is independent of particle shape in contrast to thermophoresis which varies substantially with particles of different shapes. The thermophoresis of nonspherical particles also depends on its orientation with the thermal gradient.

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: PESTAB. A method for the detection of organophosphorus pesticide residues in plants, feed, and in food products of vegetable and animal origin is described. After extraction with acetone (2x), chloroform, ethanol and chloroform, the latter extract is evaporated, the dry residue is taken up in acetone, and applied on dry indicator paper that had been treated with bromthymol blue in sodium hydroxide and with acetylcholine chloride solution. The indicator paper is dried, after which it is sprayed with 50% horse serum, and exposed to 40DEG C for 15 minutes. Organophosphorus compounds will appear in the form of dark blue rings or spots against a yellow background. The limits of detectability are 0.01 mg/kg for fenthion, valexon, dichlorvos, diazinon, amidophos, ronnel, trichlorometaphos-3, phosalone and crotoxyphos; 0.02 mg/kg for fenitrothion, and 0.05 mg/kg for chlorpyritos, malathion, methylparathion, trichlorfon, and phosmet.

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: PESTAB. Various visualizing reagents and solvents for the thin-layer chromatographic determination of organophosphorus insecticides were studied. Acetone, chloroform, hexane, benzene, and methanol were used as solvents. Detection with bromphenol blue and silver nitrate on silica gel, sodium hydroxide and silver nitrate solution, and the enzymatic method using horse serum, sodium hydroxide, bromthymol blue, and acetylcholine chloride produced rather low sensitivity for most of the pesticides tested. High sensitivity was achieved by another method using liquid petrolatum in diethyl ether on a cellulose layer for subsequent UV irradiation. The best results were obtained by separation on ready-made silufol layers and visualization with a 0. 7% solution of 2,6-dibromo-N-chloro-p-quinone imine in hexane or chloroform and subsequent simultaneous irradiation with UV and IR light. The sensitivity of this method amounted to 0. 05-0. 1 mug for most thiophosphoric and dithiophosphoric acid derivatives, but this method was not suitable for the determination of dichlorvos, naled, crufomate, crotoxyphos, and trichlorfon. A 15:5:1 ratio of hexane-acetone-chloroform is recommended as solvent system for such pesticides as trichlorfon, dimethoate, crufomate, dichlorvos, naled, crotoxyphos and phosmet. Hexane and acetone in a 4:1 ratio or a 15:5:0. 5 ratio of hexane-acetone-chlorform is recommended for fenitrothion, fenthion, diazinon, and chlorpyrifos.

Chem Codes: Chemical of Concern: PSM Rejection Code: IN VITRO.

T lymphocytes are activated by the engagement of their antigen receptors (TCRs) with complexes of peptide and major histocompatibility complex (MHC) molecules displayed on the cell surface of antigen-presenting cells (APCs) []. An unresolved question of antigen recognition by T cells is how TCR triggering actually occurs at the cell-cell contact area. We visualized T-cell-APC contact sites using confocal microscopy and three-dimensional reconstruction of z-sections. We show the rapid formation of a specialized signaling domain at the T-cell-APC contact site that is characterized by a broad and sustained area of tyrosine phosphorylation. The T-lymphocyte cell-surface molecule CD2 is rapidly recruited into this signaling domain, whereas TCRs progressively percolate from the entire T-cell surface into the phosphorylation area. Remarkably, the highly expressed phosphatase CD45 is excluded from the signaling domain. Our results indicate that physiological TCR triggering at the T-cell-APC contact site is the result of a localized alteration in the balance between cellular kinases and phosphatases. We therefore provide experimental evidence to support current models of T-cell activation based on CD45 exclusion from the TCR signaling area [, and]. http://www.sciencedirect.com/science/article/B6VRT-404HD1B-R/2/fe266785ec6b2317e889bb459f96793b

<u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: NON-ENGLISH.

ABSTRACT: Comparative studies with male rats were performed to investigate the coergism of single oral doses of selected pesticides, the comparison being based on the lethal effects observed. The quantitative analysis of the dose-mortality relationship and the determination of the coergistic index evidenced a slight increase of the lethal effect with lindane-phosmet and lindane-carbaryl combinations. The combined administration of lindane and ethylenethiourea resulted in an additive lethal effect.

769. Lewis, Edwin A. and Reams, R. Renee (1983). Histone H1: Ultracentrifugation studies of the effects of ionic strength and denaturants on the solution conformation. *Archives of Biochemistry and Biophysics* 223: 185-192.
<u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: CHEM METHODS.

The conformation of histone H1 has been examined under native and denaturing conditions in the absence of DNA or chromatin. Sedimentation coefficients were determined for Histone H1 in 0.1 KCl and in 6 guanidine hydrochloride solutions at pH 7.4. The influence of ionic strength on the conformation of histone H1 has been determined by measurement of the sedimentation coefficient in tetramethylammonium chloride solutions of up to 2.5 and extrapolated to infinite ionic strength. Results from these experiments suggest that the native conformation of histone H1 is very asymmetric in shape. The molecule is best described as a prolate ellipsoid with axes of 312 A (2a) and 16 A (2b) in low ionic strength media and also as a prolate ellipsoid with axes of 202 A (2a)

and 20 A (2b) at high ionic strength or when associated with polyanions, e.g., DNA. Denaturation of histone H1 by guanidine hydrochloride was found to be completely reversible. In 6 guanidine hydrochloride, the H1 molecule collapses to a sphere but the original extended conformation of the protein is readily restored on dialysis. This suggests rigid conformational requirements for the H1 molecule as incorporated into chromatin. The shape and dimensions for the H1 molecule at high ionic strength are not sufficiently conclusive to locate H1 in the chromatin structure. It is proposed, however, that viable models for chromatin architecture must be consistent with the histone H1 solution dimensions obtained here.

Citations: 13) Wu, L; Master thesis, Chinese Medical College 1992 Because agricultural prodn. in Taiwan depends heavily on the use of pesticides, much attention has been focused on pesticide contamination of food and on the effects of pesticide residues on human health. The Taiwan Agricultural Chems. and Toxic Substances Research Institute (TACTRI) conducts tests to evaluate the safe usage of pesticides in Taiwan. In accordance with the Pesticide Control Act, min. harvest intervals and tolerance levels for pesticides used on different crop groups are established before pesticides are approved for use in the field. The \"tolerance\" level of pesticides for different crop groups is detd. on the basis of: (i) the acceptable daily intake value of the pesticide; (ii) the av. daily consumption of each crop group by the Taiwanese people; and (iii) the level of pesticide residues on different crops, estd. from supervised trials. Tolerance levels must be established before registrations can be approved. Pesticide residues on vegetables and fruits are under heavy public scrutiny. Fifteen workstations for pesticide residue control have been set up by the TACTRI in different localities in Taiwan, and multi-residue methods are used for the anal. of these products. Pesticide residues commonly found on vegetables have now been identified. Educational programs for farmers have been devised, based on the anal. results obtained from these workstations. Risk assessments of dietary intakes of pesticides are carried out on a continuing basis. Results have shown that the dietary intake of pesticide residues by consumers is within safe limits. Pesticides are extd. from tea with acetone and methylene chloride, then enriched and cleaned up with solid phase extn. (SPE) prior to gas chromatog. detn. The fast screening is achieved by a gas chromatograph system equipped with dual-column, dual-tower auto-sampler and both electron capture detector (ECD) and flame photometric detector (FPD). Optimal conditions are investigated for the prospective pesticides including column selection, detection mode, the retention behaviors, quant. calibration, as well as the recoveries and repeatability of pesticides from tea samples. Under the optimal conditions, with the FPD-P detector accompanied CP-SIL 13CB column, 48 pesticides can be sepd. well and detected within 38 min; and with a DB-5 column, 35 ECD-detectable pesticides can be sepd. and detected within 46 min. The recoveries of 84 pesticides in tea samples are 65-120% with 0.34-16% RSD for spiking 0.02-3.0 mg/kg std. species. Because of the thermal instability of most pesticides, direct cold extn. of pesticides from a tea sample is recommended. The proposed method provided a very fast and efficient procedure to screen 84 pesticides from a complicated tea sample matrix. 772. Li, Qin, Shivachandra, Sathish B., Zhang, Zhihong, and Rao, Venigalla B. (2007). Assembly of the Small Outer Capsid Protein, Soc, on Bacteriophage T4: A Novel System for High Density Display of Multiple Large Anthrax Toxins and Foreign Proteins on Phage Capsid. *Journal of Molecular Biology* 370: 1006-1019.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

Bacteriophage T4 capsid is a prolate icosahedron composed of the major capsid protein gp23*, the vertex protein gp24*, and the portal protein gp20. Assembled on its surface are 810 molecules of the non-essential small outer capsid protein, Soc (10 kDa), and 155 molecules of the highly antigenic outer capsid protein, Hoc (39 kDa). In this study Soc, a "triplex" protein that stabilizes T4 capsid, is targeted for molecular engineering of T4 particle surface. Using a defined in vitro assembly system, anthrax toxins, protective antigen, lethal factor and their domains, fused to Soc were efficiently displayed on the capsid. Both the N and C termini of the 80 amino acid Soc polypeptide can be simultaneously used to display antigens. Proteins as large as 93 kDa can be stably anchored on the capsid through Soc-capsid interactions. Using both Soc and Hoc, up to 1662 anthrax toxin molecules are assembled on the phage T4 capsid under controlled conditions. We infer from the binding data that a relatively high affinity capsid binding site is located in the middle of the rod-shaped Soc, with the N and C termini facing the 2- and 3-fold symmetry axes of the capsid, respectively. Soc subunits interact at these interfaces, gluing the adjacent capsid protein hexamers and generating a cage-like outer scaffold. Antigen fusion does interfere with the inter-subunit interactions, but these interactions are not essential for capsid binding and antigen display. These features make the T4-Soc platform the most robust phage display system reported to date. The study offers insights into the architectural design of bacteriophage T4 virion, one of the most stable viruses known, and how its capsid surface can be engineered for novel applications in basic molecular biology and biotechnology. bacteriophage T4/ Soc/ Hoc/ virus assembly/ phage display http://www.sciencedirect.com/science/article/B6WK7-4NPG0J0-7/2/17636dbbe0fe97b10513dd3bee05ad49

Analysis of Mutagenicity of Organophosphorus Pesticides and Their Molecular Mechanism. *Zhongguo yaolixue yu dulixue zazhi* 7: 93-99.
Chem Codes: Chemical of Concern: PSM Rejection Code: MODELING.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Whole structure patternization multivariant discriminant analysis (WSPMDA) was established for studying the structure-activity relationship of mutagenicity of organophosphorus pesticides (OPPs), of which the 3 constituents were patternized in subtype patterns, and then 36 categories of structural patterns of OPPs were constructed. Predicted mutagenicity probability, P(M+), was calculated for all the categories of the structural patterns of OPPs in 6 mutagenicity tests, and the relationship between the 3 constituents and mutagenicity of OPPs was analyzed. It was found that all the 3 constituents did affect the mutagenicity of OPPs in almost all the 6 tests. The proper application of P(M+) for development of safer new OPPs was discussed. Furthermore, according to the results of WSPMDA and the principles of different tests, it is proposed that there exist 3 different ways for the molecular mechanism of mutagenicity of OPPs.

In particular, the invention concerns attractants isolated from pear or apple volatiles which have superior and selective attractancy for adult codling moths and other lepidopterous species. These attractants also attract, aggregate and/or arrest larvae of these species. The invention further concerns a method for monitoring, control, mass trapping and mating disruption of codling moth and other lepidopterous species. The method includes luring the pest to a formulation contg. the attractant, aggregant or arrestant of the invention, alone, or in combination with a sex pheromone

and/or another kairomone and/or insecticide. The attractant of the invention has the general formula CH3CH2CH2(CH2)n[C(H)=C(H)]mC(H)=C(H)C(=O)X (n = 0-8; m = 0 or 1; X = OR1, NR1R2, SR1 or R1; R1, R2 = H, C1-C6 alkyl), and is purified to at least 90% purity or a geometrical or positional isomer or deriv. thereof. Abstract: Sustainable management of percolation lakes or percolation tanks is closely related to the survival of approximately 15 million farmers and an equal number of cattle living in the semiarid basaltic plateau of western India. Here, the monsoonal rains are restricted to a few rainy days between June and September. It is therefore necessary to harvest the monsoon runoff into small percolation lakes in mini-catchments by constructing earthen bunds on small streams and allowing the stored water in the lakes to percolate and recharge the groundwater body. The residence time of water in the mini-catchments is thus increased and it is possible for the farmers to dig wells and irrigate the crops in their small farm plots. The efficiency of the percolation lakes is hampered by silt that accumulates in the lake bed or tank bed, year after year. It is therefore necessary for the benefitting farmers to desilt the lakebed when the lake dries in the summer. Soil conservation practices should be followed in the catchment area in order to reduce the amount of silt entering the lake. Non-governmental organizations play an important role in this field.

778. Lindblom, Jenny and Nordell, Bo (2007). Underground condensation of humid air for drinking water production and subsurface irrigation: EuroMed 2006 - Conference on Desalination Strategies in South Mediterranean Countries. *Desalination* 203: 417-434.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS, MODELING.

Condensation Irrigation (CI) is a combined system for solar desalination and irrigation and/or drinking water production. Solar stills are used for humidifying ambient air flowing over the saline water surface in the still. This warm, humid air is then led into an underground pipe system where it is cooled and vapour precipitates as freshwater on the pipe walls. If drainage pipes are used the condensed water and some of humid air percolate through the pipe perforations and irrigates and aerates the ground. Drinking water can be collected at the pipe endings when using non-perforated pipes. The CI system has attracted attention from several North African countries, and pilot plants are now in operation in Tunisia and Algeria. Mass and heat transfer in the soil around the buried pipes has been modelled to evaluate the theoretical potential for these types of systems and to gain understanding of the mechanisms governing their productivity. For a presumed reference system, the mean water production rate in the drinking water system was 1.8 kg per meter of pipe and day. When using drainage pipes for subsurface irrigation, this number increased to 3.1 kg/m/d, corresponding to 2.3 mm/d of supplied irrigation water. Desalination/ Irrigation/ Water production/ Heat and mass transfer/ Modelling

779. Lindblom, Jenny and Nordell, Bo (2006). Water production by underground condensation of humid air: Selected paper from the 10th Aachen Membrane Colloquium. *Desalination* 189: 248-260.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Condensation irrigation (CI) is a combined system for desalination and irrigation. By evaporating seawater in, for example, solar stills and letting the humidified air transport the formed vapour into an underground pipe system, fresh water will precipitate as the air is cooled by the ground. By using drainage pipes for underground air transportation, perforations in the pipes enable the water to percolate into the soil. This study of CI focuses on the transport of humid air inside buried plain pipes, where the condensed water stays inside the pipe and may thus be collected at the pipe endings and used for drinking. Numerical simulations of this system result in a mean water production capacity of 1.8 kg/m and day over a 50-m long pipe in a diurnally steady system, though shorter pipes result in a higher mean production. A performed theoretical analysis also indicates that CI is a promising alternative irrigation method as it enables the use of saline water for irrigation. 780. Lisovik Z, A. and Gorbacheva, N. A. (Gas-Chromatographic Determination of Metaphos, Nitrophos and Methylethylthiophos in Blood. *Farmatsiya (moscow) 26(5): 44-51 1977 (5 references).*
Chem Codes: Chemical of Concern: PSM Rejection Code: HUMAN HEALTH, CHEM METHODS.

ABSTRACT: PESTAB. A gas-chromatographic method for the quantitative determination of metaphos methyl parathion, methylnitrophos (fenitrothion) and methylethylthiophos (methylethyl paration) in human blood and peritoneal fluid obtained during peritoneal dialysis is described. Following extraction with hexane, centrifugation at 3,000 rpm and decantation, dissolution in hexane and concentration in a rotary evaporator at 20C and 0.80 kp/cm2 pressure, determination is done by means of a gas chromatograph with a SE-30-packed column and a thermionic detector. The sensitivity is 0.002 mg%; the recovery rate is 94.6-98.7% for metaphos, 94-96.1% for menthylnitrophos, and 96-98.8% for methylethylnitrophos in peritoneal fluid, and 80.4-89.3%, 81.6-88.4%, and 85.1-89.1%, respectively, in blood. The recovery rate decreases with the time elapsed after blood sampling. Therefore, the analysis should be performed as soon as possible. Substances present in commercial preparations of these pesticides (xylene, dichloroethane, vaseline and mineral oils, white spirit, emulsifiers); other organophosphorus pesticides, such as malathion, ronnel, trichlorfon dichlorvos, DEF, formothion, tetrachlorvinphos, diazinon, naled, coumaphos, demeton, menazon, phosalone, phosmet, cidial, and ciodrin, as well as the therapeutic drugs administered to patients poisoned with metaphos, methylnitrophos and methylethylthiophos are all free from interfering with the gas-chromatographic determination.

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. A multiresidue method using gas chromatography/mass spectrometry (GC) was evaluated for the determination of several pesticides in fruits and vegetables. The pesticides were extracted using a slightly modified Luke multiresidue procedure, separated by capillary column gas chromatography and detected by mass chromatography with quadrupole mass spectrometer in the electron impact mode. Recovery studies of chlorpyrifos, diazinon, endosulfan, fenarimol, fenvalerate, folpet, iprodione, malathion, methamidophos, phosmet and procymidone were performed at the 0.5 ppm spike level in cherry tomatoes, chin-chian pe-tsai, Chinese cabbages, kidney beans and oranges. Recoveries were between 64.6 and 124.6%, with the exception of methamidophos which produced interference due to the constituents of the samples. Coefficients of variation ranged between 0.3 and 17.6%, with an average of 5.3%. The estimated limits of detection of the pesticides (except methamidophos) in the crops were at

Chem Codes: Chemical of Concern: PSM Rejection Code: NON-ENGLISH.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. A two-year survey shows that bulb mites are important soil pests on floral bulbs in Taichung area. Among the three mites observed, Rhizogiyphus robini was the most prevalent and constituted > 95% of the bulb mites found. This survey also shows that gladiolus and lily were the most vulnerable and the damage could reach > 90% when no measure was taken. With proper control, an average of 12.6% or 6.8% of the bulbs was still affected. The chlorosis of these plants often resulted from the simultaneous occurrence of bulb mites and bacterial diseases, further suggesting the seriousness of these pests. Continuous culture enhanced the occurrence of and damage inflicted by bulb mites. Our Station first proposed soaking the bulbs in chemical solutions for 1/2 and 1 hr in order to control these bulb mites. Checking the results 1, 4 and 7 days after the treatment revealed that among the twenty chemicals tested, two of the currently recommended, i.e., 25% Bromopropylate E. C. (4

The novel fungal organophosphate hydrolase (I) was purified to homogeneity and characterized, and found to hydrolyze methyl parathion, parathion, paraoxon, coumaphos, demeton-S, phosmet, and malathion. I was monomeric with a mol. wt. of 60 kDa, a pI of 4.8, and enzyme activity was optimal at 45 Deg and pH 7.5. I was strongly inhibited by Hg^{2+}, Fe^{3+}, p-chloromercuribenzoate, iodoacetate, and N-ethylmaleimide, whereas Cu^{2+}, b-mercaptoethanol, dithiothreitol, dithioerythritol, glutathione, and detergents slightly activated the enzyme. As judged by catalytic efficiencies, paraoxon was the preferred substrate. Thus, this appears to be the 1st broad-spectrum I purified to homogeneity from fungi, which effectively degrades organophosphorus pesticides contg. both P-O and P-S linkages. ABSTRACT: Children up to 6 years of age who lived with pesticide applicators were monitored for increased risk of pesticide exposure: 48 pesticide applicator and 14 reference families were recruited from an agricultural region of Washington State in June 1995. A total of 160 spot urine samples were collected from 88 children, including repeated measures 3-7 days apart. Samples were assayed by gas chromatography flame photometric detector for dimethylphosphate metabolites. Dimethylthiophosphate (DMTP) was the dominant metabolite. DMTP levels were significantly higher in applicator children than in reference children ($p = 0.015$), with median

concentrations of 0.021 and 0.005 microg/ml, respectively; maximum concentrations were 0.44 and 0.10 microg/ml, respectively. Percentages of detectable samples were 47% for applicator children and 27% for reference children. A marginally significant trend of increasing concentration was observed with decreasing age among applicator children (p = 0.060), and younger children within these families had significantly higher concentrations when compared to their older siblings (p = 0.040). Applicator children living less than 200 feet from an orchard were associated with higher frequency of detectable DMTP levels than nonproximal applicator children (p =0.036). These results indicate that applicator children experienced higher organophosphorus pesticide exposures than did reference children in the same community and that proximity to spraying is an important contributor to such exposures. Trends related to age suggest that child activity is an important variable for exposure. It is unlikely that any of the observed exposures posed a hazard of acute intoxication. This study points to the need for a more detailed understanding of pesticide exposure pathways for children of agricultural workers.

Azinphos Me was the main pesticide applied and it was detected with the highest frequency in groundwater wells during the period of intensive pesticide application in the Southern Hemisphere. Dimethoate, methidathion, fosmet, cipermethrin, carbaryl, propoxur, carbofuran, benomyl and carbendazim were also detected with lower frequency. The characteristic of the area under study was alk. soil, with an org. matter content <2.5% and texture sandy clay loam. The half life of azinphos Me in soils was 166.2 days in the sun light for horizon A and 194.15 in the dark for horizon B. Leaching of azinphos Me through the different soil horizons was min. On the basis of our lysimeter lab. data, in which most of the pesticide was adsorbed into the soil column and only small quantities leachate, we inferred that the impact of azinphos Me on groundwater would be minimal. However, field data indicate that there is a persistence of azinphos Me in groundwater during the application season. [on SciFinder (R)] 0048-9697 groundwater/ pollution/ azinphos/ methyl/ Argentina

As a consequence of the leaching process, groundwater from the Valley of Neuquen River frequently contained concns. of organophosphorus pesticides that exceeded acute toxicity risk ratios established to protect aquatic life. It was found that some pesticides, as azinphos Me, had a high detection frequency, 66% of the samples, with concns. varying from no detection to 48.9 ppb. Dimethoate, methidathion and phosmet were also detected with frequencies of 14.1, 13.6 and 10.8% and with concn. ranks from no detection to a max. value of 10.9, 2.0 and 15.5 ppb, resp. Seasonal variations and temporal trends were found for these compds. in groundwater. [on SciFinder (R)] 0360-1234 pesticide/ fruit/ orchard/ shallow/ groundwater

ABSTRACT: Spraying of spring wheat plants during vegetation with herbicides of 2,4-D group and ethrel increased chromosome aberrations in meiosis 2.8-5, 3.6-4.1 times. The insecticides, chlorophos and phtalophos, in a little higher dosage than it is usually practised increased the spontaneous level of chromosome aberrations 3.1-5.5 times. Phtalophos also induced chlorophyll mutations. These results testify to the necessity of keeping strictly to the established normative doses, because of overdosage is of potential genetic danger to spring wheat crops.

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. A stability study of 44 organochlorine pesticides (OCPs) and 47 organophosphorus pesticides (OPPs) was conducted. Compounds were spiked into solvent only (hexane-acetone, 1 + 1; methylene chloride-acetone, 1 + 1; methyl tert-butyl ether (MTBE); and toluene-methanol, 10 + 1), solvent/dry soil suspensions, and solvent/wet soil suspensions (20% water, w/w). Spiked matrixes were heated in closed vessels with microwave energy at 2 temperatures (50ę and 145ęC) for 5 or 20 min. For comparison and for determination of nitrogen blowdown losses, spiked matrixes that had not been exposed to microwave energy were concentrated by using the blowdown technique and analyzed for each of the spiked compounds. For OCPs, temperature had the most significant effect on compound recovery, followed by matrix. All 3 pairwise comparisons of the 3 matrix types were statistically significant. The solvent factor was also significant, with average recoveries of 97.8% with methylene chloride acetone,

33213-65-9 (Endosulfan II); 34643-46-4 (Tokuthion); 35400-43-2 (Bolstar); 39765-80-5 (trans-Nonachlor); 53494-70-5 (Endrin ketone); 61949-77-7 (trans-Permethrin) Role: ANT (Analyte), ANST (Analytical study) (detn. of, in soils and sediment materials, supercrit. fluid extn. in); 7631-86-9 Role: BIOL (Biological study) (sand, pesticide and polycyclic arom. hydrocarbon detn. in, supercrit. fluid extn. in) Sand, spiked with 41 organochlorine pesticides and 47 organophosphorus pesticides, is extd. with supercrit. CO2 at various pressures and temps., and the recoveries are detd. Two std. ref. materials certified for polynuclear arom. hydrocarbons are extd. under supercrit. conditions, and the data are compared with the certified values which have been detd. by conventional extn. techniques. There is a large discrepancy between the resulting data and the certified values. To explain the discrepancy, a preliminary method optimization study is conducted in which the influences on recoveries of seven variables are investigated. The study allows estn. of the main effects of the seven variables; however, the authors could not test the statistical significance of any of these effects. The results from the preliminary method optimization expts. indicate that, under the conditions used, recovery is most affected by extn. time and extn. pressure, followed by moisture content of the material and sample size. Finally, the approx. costs assocd. with setting up and using a supercrit. fluid extn. system in an anal. lab. are presented and are compared with those for Soxhlet extn. (SPME). Three fibers, including a 15-mm XAD-coated fiber, a 85-mm polyacrylate-coated fiber, and a 30-mm polydimethylsiloxane-coated fiber (PDMS), were evaluated here. The effects of stirring and the addn. of NaCl to the sample were examd. for the polyacrylate-coated fiber. The precision of the technique was examd. for all 3 fibers and the extn. kinetics were investigated using the XAD- and polyacrylate-coated fibers. With some exceptions, the XAD- and polyacrylate-coated fibers performed better than the PDMS-coated fiber. The superiority of the XAD- and polyacrylate-coated fibers over the PDMS-coated fiber can be attributed to the arom. functionalities of the XAD and the polar functionalities in the polyacrylate. The relatively high RSDs indicated that the SPME technique needs to be further refined before it can be used for anything other than screening. A more effective form of agitation than mech. stirring may be necessary to reduce variability and to achieve a faster equil. between the sample and the SPME fiber. not subjected to any clean-up procedure. The organophosphorus insecticide residues were detd. by GC with flame photometric detection and AT - 1701 capillary column was used for the temp. - programmed chromatog. detn. of pesticide residues. High recoveries of 8 organophosphorus insecticides fortified at 0.01, 0.1, and 1.0 mg kg-1 were obtained. The limit of detection ranged from 0.0020 to 0.016 5 ng. This method was simple, rapid with good reproducibility. [on SciFinder (R)] 0254-1793 capillary/ gas/ chromatog/ organophosphorus/ pesticide/ Tianhuafen

793. Louzao, M. J., Leiros, M. C., and Guitian, F. (1990). Study of Buffering Systems in Soils From Galicia, Northwest Spain. *Water air soil pollut* 49: 17-34.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. The effects of acid rain on surface horizon of five soils from Galicia and the buffer capacity of these soils with respect to the addition of H+ were studied. Soil samples were placed in percolating tubes with a diameter of 7.5 cm. The diluted acid treatment, composed of distilled water acidified with HCl to a pH value of 3, was applied to each duplicate soil core at a drip-rate of 2.8 mL min-1, for 8 hr d-1 over 18 days. The acid addition produced an associated leachate of both organic and inorganic anions and cations, although behavior patterns differed: a quick leach of labile forms (probably soluble forms) and a slower leach of more retained form (most likely to be exchangeable forms and/or products dissolved from solid phases). The organic C decreased and the N increased as the percolates became more acidic. The neutralizing mechanisms for each of the soils used in the experiment corresponded in general terms to the buffer capacity that was to be expected given the

ABSTRACT: Androgen receptors (AR) have been identified in the human endometrium, but their role in endometrial function and development towards endometrial receptivity remains poorly understood. In an effort to study the regulation and possible function in endometrial epithelium, we utilized the well-differentiated endometrial adenocarcinoma cell line, Ishikawa, as a model system. This cell line has proven to be stable, hormonally responsive, contains both estrogen and progesterone receptors, and has been shown to express endometrial proteins in a hormone responsive manner. In the present study, we demonstrate that Ishikawa cells also express AR,

based on immunohistochemical staining, radioactive binding studies, RT-PCR and Northern blot analysis. The expression of AR is induced in Ishikawa cells by estrogens, similar to that reported for normal endometrium. Further, using an estrogen-responsive gene that has been characterized in this cell line, alkaline phosphatase, we show that androgens act as antiestrogens in diethylstilbestrol (DES) treated cells, inhibiting enzymatic activity in a dose-dependent manner. These data support a physiologic role for AR in the endometrium. Elevations in endometrial AR in certain clinical situations such as polycystic ovarian syndrome (PCOS) may amplify the effects of androgens on the endometrium leading to suspected defects in uterine receptivity, higher than expected infertility and high miscarriage rates observed in patients with this disorder.

796. Lovenstein, H. M., Berliner, P. R., and van Keulen, H. (1991). Runoff agroforestry in arid lands. *Forest Ecology and Management* 45: 59-70.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

Biomass production in arid zones may be increased without irrigation by using runoff farming techniques. The salient feature of this technique is that large amounts of water are collected a few times per year and percolate deep into the soil. The combined cultivation of shallow rooting annuals and deep rooting perennials (agroforestry) was proposed as a method by which fodder and firewood could be simultaneously produced and stored water used efficiently. As a first step to test the feasibility of this proposal, Acacia salicina and Eucalyptus occidentalis were grown at two densities (625 and 1250 trees ha-1) in runoff catchment basins in the Northern Negev Desert of Israel (average rainfall: 115 mm a-1). Biomass, soil moisture content and some plant physiological parameters were periodically recorded. Total above-ground dry matter after three years was 15 and 19 t ha-1 for A. salicina and 25 and 28 t ha-1 for E. occidentalis at low and high density, respectively. Soil water balance studies during the growing season indicate that for the conditions under which this trial was carried out, tree roots do not explore the upper soil layers efficiently and that relatively high leaf water potential can be maintained by taking up water from deeper layers. These results suggest that water from surface layers could be used by annual crops without affecting production of the perennial crop. http://www.sciencedirect.com/science/article/B6T6X-48XMKY9-YG/2/626f978fd6aa83f58733d481ddbd9983

797. Loyalka, S. K. and Griffin, J. L. (1994). Rotation of non-spherical axi-symmetric particles in the slip regime. *Journal of Aerosol Science* 25: 509-525.

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Aerosol particles are often non-spherical, and the shape has an important influence on the frictional drag and torque, and hence the Brownian motion, the deposition, the sampling and the coagulation of the particles. Since the particle sizes of interest span a wide range, it is important to have experimental as well as theoretical understanding of the frictional drag and torque for particles of arbitrary shapes and sizes. It is also desirable to know the extent to which some useful shape factors can be defined. In recent years there has been considerable progress in the study of non-spherical particles in the continuum regime (low Reynolds number hydrodynamics), and the problem of frictional torque has been solved numerically. This paper addresses the problem of frictional torque of non-spherical axi-symmetric particles at low Reynolds number but with slip boundary conditions. The use of slip boundary conditions is pertinent in aerosol dynamics as it permits consideration of particles in an important size range, where use of a zero slip condition cannot be justified, especially locally, because of the large curvatures of some non-spherical particles. The slip condition does introduce a few complications, both conceptual and numerical. This paper shows that the problem of the rotation of non-spherical axi-symmetric particles with slip conditions can be converted to an integral equation, which can be solved quite effectively by subtraction of singularity and use of quadrature techniques. As an example, numerical results for spheroids (oblate/prolate) are reported, and are shown to be in excellent agreement with analytical results obtained through series expansions. First order approximations to the solution of the underlying equations are given and dependence of the torque on the aspect ratio and Knudsen number is also explored. http://www.sciencedirect.com/science/article/B6V6B-4893VYW-3H/2/db02e0dfa1f44c769a69925a44266cf4

Citations: Whelan, E; Am J Public Health 1997, 87, 1352 Children's exposure to organophosphorus (OP) pesticides in an agricultural community in central Washington State was detd. Spot urine and hand wipe samples were collected from 109 children 9 mo to 6 yr of age, as were house dust samples and wipe samples from various surfaces. Children were categorized based on parental occupation (agricultural vs. nonagricultural) and on household proximity to pesticide-treated orchards. Median house dust concns. of di-Me OP pesticides in homes of agricultural families were seven times higher than in those of ref. families (1.92 vs 0.27 mg/g; P <0.001). Median pesticide metabolite concns. in agricultural children were five times higher than those in ref. children (0.05 vs 0.01 mg/mL; P = 0.09). Median pesticide concns. in house dust (P = 0.01) and metabolite concns. in urine (P = 0.01) from agricultural families were significantly higher in the children living near treated orchards (within 200 ft or 60 m) than those living more distant. Ten of 61 agricultural children had detectable OP pesticide levels on their hands, whereas none of the ref. children had detectable levels. These findings indicate that children living with parents who work with agricultural pesticides or who live in proximity to pesticide-treated farmland have higher exposures than do other children living in the same community. This study reports QSAR models for predicting enzymic activity of chloroperoxidase on metabolizing selected organophosphorus pesticides (OPPs). The authors used ten quantum chem. descriptors computed with the ab initio method at HF/6-31G(d) level and partial least squares (PLS) anal. with optimizing procedure for generating QSAR models. The correlation coeff. of the optimal model was 0.918, and the fitting results showed that it had high fitting precision and good predicting ability. The PLS assistant anal. indicated that the at. charges of sulfur and phosphorus atoms in the S:P bond of an OPP mol. were important in governing the enzymic activity, and the mol. dipole moment also had some effect on the enzymic activity. OPPs with high abs. values of at. charges on the sulfur and phosphorus atoms tended to be metabolized faster, whereas OPPs with stronger polarity tended to be metabolized slower by chloroperoxidase. The optimal model was used to predict the enzymic activity of two OPPs, and the results appeared to be reasonable. The single, rapid, multiresidue method of M. A. Luke et al. (1983), with appropriate modifications, was used. The data were compiled to show the commodities sampled and the identity and range of levels of pesticide residues detected, including an indication of those residue findings that did not comply with U.S. federal tolerance levels. The residue data presented are not representative of the U.S. food supply; rather, the results are indicative of a surveillance- and compliance-oriented sampling of various food shipments collected by the Los Angeles District.

804. Luke, Robert L. (1984). Glomerular permselection: Shape and flow. *Journal of Theoretical Biology* 106: 141-156.
Chem Codes: Chemical of Concern: PSM Rejection Code: MODELING.

The selective permeability of the glomerular basement membrane to macromolecules is a function of the size and charge of the macromolecule. Evidence suggests that shape may also be a factor. The orientation of macromolecules in solution is dependent on their size, shape, and frictional interactions with moving solvent molecules. The spaces between the glomerular visceral epithelial cells (slit pores) may produce a non-uniform distribution of fluid flow within the basement membrane, and this non-uniformity may increase during disease. This report is of a model that relates the filtration of rigid prolate ellipsoidal (cigar) shaped macromolecules to the size and shape of the filter and to the velocity of solvent flow. The calculations, using published macromolecular and glomerular parameters correspond well to published data. The glomerular visceral epithelial cell, by altering the number, size and distribution of the intercellular spaces, may regulate the passage of ellipsoidal shaped macromolecules, such as albumin and IgG, into and through glomerular structures. http://www.sciencedirect.com/science/article/B6WMD-4F1SV94-4B/2/5450eb76399e0a48c545ba112ee61b9c

805. Luo, Y., Qiao, X., Song, J., Christie, P., and Wong, M. (Use of a Multi-Layer Column Device for Study on Leachability of Nitrate in Sludge-Amended Soils. *Chemosphere. 2003, sep; 52(9):1483-8. [Chemosphere]: Chemosphere*.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE, CHEM METHODS.

ABSTRACT: This paper described a multi-layer column device constructed with six cylindrical polythene tubes with installation of Rhizon soil moisture samplers (Rhizon SMS). The feasibility of using the column device to collect soil solution and percolate and to monitor leachability of nitrate in two sludge-amended soils was evaluated under glasshouse conditions. The soil moisture sampler in the device was demonstrated to be a non-destructive, simultaneous, sequential, convenient and rapid sampling tool for multiple-site porewater extraction. The device provided an in situ monitoring technique for leachability of nitrate in a soil profile following application of the anaerobically digested sewage sludge. The monitored results showed that surface soil amendment of the sewage sludge increased markedly the concentration of nitrate in the soil solutions at depths of 10-30 cm in a neutral paddy soil and at 30-50 cm in an acid red paddy soil. This amendment also largely increased nitrate in the percolates of the acid red soil. The movement and distribution patterns of nitrate in the profile were related to soil types, profile depths and experimental periods. Land application of sewage sludge may pose a risk in groundwater contamination of nitrate.

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE, MODELING.

ABSTRACT: In this work a mathematical model has been developed and used to estimate the soil vertical distribution of Atrazine dispersed in the environment. Water transport, rise due to capillarity, and partition among soil-contained water, air, and organic matter, as well as degradation processes, are considered. As far as the vertical mobility in soil is concerned, the model has been derived from that proposed by P. H. Nichols, A. Walker, and R. J. Baker [1982). Pestic. Sci. 12, 484-494). Such a model has been extended to include a procedure which takes into account the Atrazine mobility due to gravitational water flow. The organic carbon (O.C.) concentration gradient in soil was also considered in the evaluation when assessing partition processes, according to models by P. J. McCall et al. [1983). Residue Rev. 13, 231-241) and D. McKay and S. Paterson [1982). Environ. Sci. Technol. 16, 12, 654). The degradation processes are assumed to be first order, linearly related with O.C. content in soil. The application of this model to two sets of soil data demonstrated that Atrazine requires a long time (2 years or more, depending on soil features) in order to percolate at a depth comparable with those of a groundwater source.

Coden: 69FWBR
Language: written in English. Improving anal. of pesticides in matrixes requires advances in sample handling and detection. Higher flow capacity of newer GCMS systems allow higher sample loading flow with programmed septum purge for the injection port. Improved system inertness and sensitivity dramatically increases detection capability. Samples were prepd. and submitted by the USDA Research Facility, Idaho. A Shimadzu QP-2010 GCMS was used in EI mode with std. GC-2010 with split/splitless injection. The column was a Restek XTI-5 30m x 0.25mm id x 0.25um phase. A Siltex liner for the GC-2010 was substituted during the anal. process. Samples were injected while the injection port was initially set to 150 DegC then ramped to 290 DegC. The injection port was coated with fused silica by Entech Instruments. The following compds.(retention times and ions for quantitation and confirmation)were analyzed: Etridasole 211.00 (100) 183.00 (80) 196.00 (220) Nitrapyrin 196.00 (100) 198 (36) Ethoprop 158.00 (100) 200 (45) 242.00 (28) 192.00 (8) Monocrotophos 127.00 (100) 193.00(30)109.00(12)121.00 (25) Phorate 75.00 (100) 97.0 (24). Dimethoate 87.00 (100) 93.00 (60) 125.00 (40) Metolachlor 162.05 (100) 238.00 (55) Dacthal 300.80 (100) 299.00 (82) Imazamthabenz 256.00 (100) 214.00 (60) Tebuconazole 250.00 (100) 252 (30) 125.00 (190) Propinconazole 173.00 (100) 175 (70) 259.00 (50) Captafol 75.00 (100) 80.00 (35) Phosmet 160.00 (100)161.00(13)133.00(40)104.00(20). Azinphos-Me 160.00 (100) 132.00 (95)125.00 (25) LamdaCyhalothrin181.00 (100) Permethrin 183.00 (100) 162.95 (25) Cyfluthrin 226.00 (100) 227.00 (25) Fenvalerate 419.00 (100) 167.00 (300) 225.00 (150). Under these conditions, the detection limit was less than 1ppb for a 99% confidence level correct identification by retention time and m/z. The substituted Siltex liner was more effective in eliminating formation of active sites that cause injection system losses. In addn., GCMS stability of ion generation and flow stability were found to be crit. to the success of this anal. [on SciFinder (R)]

<u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: FATE.

ABSTRACT: TD3: A 5m sediment core from L. Lomond, in which a well defined band of marine sediment resulting from the Flandrian marine transgression is present, was extensively analysed by INAA, XRF and alpha -spectrometric techniques. Approximately 10 exp 3 concentration data points for elements including Na, K, As, Br, I, La, Sm, Sc, Cr, Fe, Co, Rb, Sb, Cs, Ce, Eu, Tb, Lu, Hf, Ta, U, Th and Ra are presented. From this large data set, some generalisations on the geochemistry of particular groups of elements (on a periodic table classification) are obtained. In addition, sorption data for Cs, Sr, Ce, Co, I, Tc and Np onto bulk samples of lacustrine and marine sediment were measured and analysed in terms of the expected speciation of these elements under experimental conditions. Using simple models of element remobilisation by diffusive and advective processes it is shown that the elemental profiles observed in-situ are not readily explained by variations in measured sorption. Of particular relevance is the appa

(Current Considerations on the Relative Importance of Conducting Additional Studies on Hazards of Field Worker Exposure to Pesticide Residues as Compared to Studying Other Occupational Safety Hazards on the Farm. *In: pesticide residue hazards to farm workers, niosh 76-191 p. 125-142 1976 (5 references).*
Chem Codes: Chemical of Concern: PSM Rejection Code: HUMAN HEALTH.

ABSTRACT: PESTAB. Surveys of farm safety, although often poorly conducted, show that there is a larger incidence of occupational injuries than occupational diseases. In California during 1973 to 1975, there were no pesticide deaths. The testing of pesticide dangers and the experience in the use of various safety regulations has allowed California to enact a Pesticide Safety Regulation Code. This cose delineates precautions, reentry times, and other health regulations with regards to pesticides and their use. The only residue poisoning case occurred in 1973, and resulted from the repeated exposure to numerous pesticide residues (ethion, Imidan (phosmet), phosalone, and dialifor) that were all well below the legal limits. Reentry times should be continually examined and changed as necessary. The control of pesticides before application is also examined, with the use of closed mixing systems suggested. The study of farm safety still needs accurate data for the continued assessment of the contamination problem.

814. Maestre, Fernando T., Huesca, Mayte, Zaady, Eli, Bautista, Susana, and Cortina, Jordi (2002). Infiltration, penetration resistance and microphytic crust composition in contrasted microsites within a Mediterranean semi-arid steppe. *Soil Biology and Biochemistry* 34: 895-898.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

In semi-arid areas with sparse vegetation cover, runoff generated in the open areas is crucial for the maintenance of vegetated patches. Microphytic crusts play a major role in this redistribution of water, thus influencing ecosystem functioning and dynamics. We investigated the effects of alpha grass (Stipa tenacissima L.) on the composition of the microphytic crusts, surface soil compaction, and infiltration in a semi-arid steppe of SE Spain. The microphytic crust composition differed between the upslope of S. tenacissima tussocks (tussock microsites) and the inter-tussock areas with sparse vascular plant cover (open microsites), with more moss cover in the tussock microsite, and more cyanobacteria and lichens in the open microsite. The surface soil compaction was higher in the open microsite. Variables related with infiltration showed a clear microsite effect, with higher infiltration rate and less time required by first drop to percolate in the tussock microsite. Partial correlation analysis showed a significant negative relationship between the cyanobacteria cover and the infiltration rate, and both the cyanobacteria cover and the percentage of bare soil showed a significant positive relationship with the time required for first drop to percolate. Our results reinforce the idea that open microsites act as sources of water for S. tenacissima tussocks. This study helps to understand the interactions between microphytic crusts and vascular plants in semi-arid environments. ABSTRACT: Land application of animal manure is an important means of utilization of nitrogen and phosphorus. However, the presence of pathogens in manure and their occasional leaching into subsurface water has become a topic of concern during the past few years. This study was undertaken to determine the extent to which Salmonella anatum may leach through tile-drained clay loam soil on which swine manure has been applied. For this purpose, swine manure was experimentally contaminated with S. anatum and applied to three tile-drained plots in winter of 2001 while another three plots served as negative controls. Following rainfall events in the spring of 2002 the tiles started to flow and leachate samples of subsurface water were collected at various time intervals and tested for S. anatum. Salmonella anatum was not found to leach into the subsurface drainage water indicating that it was either retained in the upper layers of soil or did not survive over winter. The leaching of faecal coliforms and coliphages was also tested. Faecal coliforms and coliphages were detected in the subsurface water from both manure and control plots, indicating the ability of the tile drainage system to transport these organisms to groundwater as the water percolates through the soil. Additional temporal studies over a longer time period are needed to determine the survival and leaching of pathogens and indicators into subsurface water.

(Orthene); 55098-00-5 (S-Methyl-bis-fenitrothion) Role: ANT (Analyte), ANST (Analytical study) (detn. of, by gas chromatog., megabore columns in) A conventional packed-column chromatograph was modified for use with a megabore column using a com. conversion kit, with the intention of developing a multi-residue method for organophosphorus pesticides. The conversion does not affect the resolving power of the megabore column, since 14 organophosphorus pesticides could be sepd. in a single injection. The megabore column in such a system proved to much more efficient than a packed column in terms of resoln. and qual. reproducibility, and comparable with a similar column in a dedicated chromatograph. However, the conversion did affect the quant. reproducibility of the system to some degree, as indicated by coeffs. of variation between 5 and 27%, although it was detd. that the particular nitrogen-phosphorus detector system (filament bead) used was partly responsible for the variation. Nevertheless, calibration curves were obtained down to 0.1 ng per component, and a limit of quantitation of 1.0 ng was established for each component in a sample contg. 14 organophosphorus compds. The retention times varied from 0.9 min (dichlorvos) to 24.3 min (phosmet) and limits of detection varied between 0.01 and 0.08. Thus, the system is sufficiently reproducible to develop a multi-residue method for organophosphorus pesticides in environmental waters. (Amberlite XAD resins) were studied for the multiresidue recovery of fourteen organophosphorus compds. in water. Extn. with Et acetate in a salted medium provided the most consistent data, both in terms of no. of compds. recovered and percentage recovery. Amberlite XAD resins gave consistently high recoveries, and this was attributed to a matrix effect upon the particular nitrogen-phosphorus detector. The evaluation was made using a megabore column installed in a conventional packed-column

chromatograph, and the results show that such a system is amenable to the multiresidue anal. of organophosphorus pesticides at very low cost. [on SciFinder (R)] 0021-9673 pesticide/ detn/ water/ gas/ chromatog

821. Malone, R. W., Logsdon, S., Shipitalo, M. J., Weatherington-Rice, J., Ahuja, L., and Ma, L. (2003). Tillage effect on macroporosity and herbicide transport in percolate: Quantifying agricultural management effects on soil properties and processes. *Geoderma* 116: 191-215.
Chem Codes: Chemical of Concern: PSM Rejection Code: MODELING.

Research suggests that pesticide transport to tile drains and shallow groundwater may be greater for no-till than tilled soil. Also, most pesticide transport through soil can be from macropore flow, but the effect of tillage on macropore transport is uncertain. Our objective was to investigate the effect of tillage on herbicide leaching through hydraulically active macropores. The number of percolate-producing macropores at 30 cm (nmacro) and the timing of initial percolate were measured from an experiment where atrazine, alachlor and rainfall were applied to moldboard plowed (MP) and no-till (NT) undisturbed soil blocks from two different silt loam soils. Alachlor and atrazine transport through the undisturbed soil blocks was simulated using the Root Zone Water Quality Model (RZWQM). The time of initial percolate breakthrough at 30 cm was significantly less for NT than for MP ($p<0.001$), but nmacro was not significantly different between MP and NT treatments. Additionally, nmacro was significantly different between the two silt loam soils ($p<0.001$). Multiple linear regression revealed that flow-weighted herbicide concentration in percolate decreased with increasing nmacro (cm-2) and increasing time for initial percolate breakthrough (min) (R2=0.87 for alachlor and 0.85 for atrazine). Because a small fraction of nmacro produces the majority of percolate, we used half of measured nmacro for RZWQM input. Also, soil parameters were calibrated to accurately simulate the water flow component timing of percolate arrival and percolate amount through macropores. This parameterization strategy resulted in accurate predicted herbicide concentrations in percolate at 30 cm using RZWQM (within the range of observations). The modeling results suggest that differences in soil properties other than macroporosity such as a lower soil matrix saturated hydraulic conductivity and porosity in subsurface soil (8-30 cm) can cause percolate to occur sooner through macropores on NT than on MP and cause higher herbicide concentrations in percolate on NT, even when nmacro does not differ between till and no-till. ABSTRACT: Due to the complex nature of pesticide transport, process-based models can be difficult to use. For example, pesticide transport can be effected by macropore flow, and can be further complicated by sorption, desorption and degradation occurring at different rates in different soil compartments. We have used the Root Zone Water Quality Model (RZWQM) to investigate these phenomena with field data that included two management conditions (till and no-till) and metribuzin concentrations in percolate, runoff and soil. Metribuzin degradation and transport were simulated using three pesticide sorption models available in RZWQM: (a) instantaneous equilibrium-only (EO); (b) equilibrium-kinetic (EK, includes sites with slow desorption and no degradation); (c) equilibrium-bound (EB, includes irreversibly bound sites with relatively slow degradation). Site-specific RZWQM input included water retention curves from four soil depths, saturated hydraulic conductivity from four soil depths and the metribuzin partition coefficient. The calibrated parameters were macropore radius, surface crust saturated hydraulic conductivity, kinetic parameters, irreversible binding parameters and metribuzin half-life. The results indicate that (1) simulated metribuzin persistence was more accurate using the EK (root mean square error, RMSE = 0.03 kg ha(-1)) and EB (RMSE = 0.03 kg ha(-1)) sorption models compared to the EO (RMSE = 0.08 kg ha(-1)) model because of slowing metribuzin degradation rate with time and (2) simulating macropore flow resulted in prediction of metribuzin transport in percolate over the simulation period within a factor of two of that observed using all three pesticide sorption models. Moreover, little difference in simulated daily transport was observed between the three pesticide sorption models, except that the EB model substantially under-predicted metribuzin transport in runoff and percolate >30 days after application when transported concentrations were relatively low. This suggests that when macropore flow and hydrology are accurately simulated, metribuzin transport in the field may be adequately simulated using a relatively simple, equilibrium-only pesticide model.

Abstract: Contaminant transport models should be evaluated over a wide range of conditions to determine their limitations. The models PRZM and GLEAMS have been evaluated many times, but few studies are available in which predicted movement in runoff and percolate were simultaneously evaluated against field data. Studies of this type are essential because pesticide leaching and runoff are mutually dependent processes. For this reason, PRZM-3 and GLEAMS

were evaluated for their ability to predict metribuzin concentrations in runoff, sediment, subsurface soil, and pan lysimeters under three field conditions (yard waste compost amended, no-till, and conventional-till) on a Lowell silt loam soil. Sensitive input parameters were either site specific (climatic, soil, and chemical) or calibrated (K-factor, C-factor, curve number). In general, both models under-predicted metribuzin concentration in runoff water, runoff sediment, subplow layer soil (15-75 cm), and pan lysimeter water (75 cm). Contrary to field data, both models predicted that a large percentage (greater than 50%) of metribuzin would move below the 'mixing zone' (top 1 cm) during the first rainfall event after application. Relatively little metribuzin was predicted to move beyond the plow layer (top 15 cm) into the pan lysimeters or subsurface soil throughout the simulation period, possibly due to the lack of a macropore component in the models. High metribuzin concentrations in sediment (field data) indicated that relatively little metribuzin moved below the 'mixing zone', possibly because of hysteresis but much of the metribuzin that did move was quickly transported into the pan lysimeters, probably due to macropore flow. GLEAMS more accurately predicted pesticide concentration in sediment and PRZM predicted subsurface soil concentration somewhat more accurately than GLEAMS. Little difference in accuracy was detected between models on metribuzin concentration in runoff or metribuzin concentration in percolate. Although both models generally under-predicted metribuzin concentration in runoff, runoff transport (mass of metribuzin in runoff) for the study period was over-predicted by both models which emphasizes the importance of accurately predicting herbicide concentration and runoff volume soon after application when the surface pesticide concentrations are highest.

(Herbicide Leaching as Affected by Macropore Flow and Within-Storm Rainfall Intensity Variation: a Rzwqm Simulation. *Pest manag sci. 2004, mar; 60(3):277-85. [Pest management science]: Pest Manag Sci.*
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: Within-event variability in rainfall intensity may affect pesticide leaching rates in soil, but most laboratory studies of pesticide leaching use a rainfall simulator operating at constant rainfall intensity, or cover the soil with ponded water. This is especially true in experiments where macropores are present--macroporous soils present experimental complexities enough without the added complexity of variable rainfall intensity. One way to get around this difficulty is to use a suitable pesticide transport model, calibrate it to describe accurately a fixed-intensity experiment, and then explore the affects of within-event rainfall intensity variation on pesticide leaching through macropores. We used the Root Zone Water Quality Model (RZWQM) to investigate the effect of variable rainfall intensity on alachlor and atrazine transport through macropores. Data were used from an experiment in which atrazine and alachlor were surface-applied to 30 x 30 x 30 cm undisturbed blocks of two macroporous silt loam soils from glacial till regions. One hour later the blocks were subjected to 30-mm simulated rain with constant intensity for 0.5 h. Percolate was collected and analyzed from 64 square cells at the base of the blocks. RZWQM was calibrated to describe accurately the atrazine and alachlor leaching data, and then a median Mid-west variable-intensity storm, in which the initial intensity was high, was simulated. The variable-intensity storm more than quadrupled alachlor losses and almost doubled atrazine losses in one soil over the constant-intensity storm of the same total depth. Also rainfall intensity may affect percolate-producing macroporosity and consequently pesticide transport through macropores. For example, under variable rainfall intensity RZWQM predicted the alachlor concentration to be 2.7 microg

ml(-1) with an effective macroporosity of 2.2 E(-4) cm(3) cm(-3) and 1.4 microg ml(-1) with an effective macroporosity of 4.6 E(-4) cm(3) cm(-3). Percolate-producing macroporosity and herbicide leaching under different rainfall intensity patterns, however, are not well understood. Clearly, further investigation of rainfall intensity variation on pesticide leaching through macropores is needed.

Abstract: We recognize a new genus of Nyssaceae on the basis of abundant foliage and reproductive remains from the Paleocene of North America. Browniea gen. n. is known from leaves, inflorescences, and fruits co-occurring in at least 30 sites in Wyoming, Montana, North and South Dakota, Saskatchewan, and Alberta, ranging from Maastrichtian to uppermost Clarkforkian. The simple, serrate leaves of Browniea serrata (Newberry) comb. n. were previously referred to such diverse genera as Alnus, Amelancier, Celastrus, Eucommia, Tapiscia, and Viburnum. Inflorescences and infructescences are globose heads borne on long, slender peduncles. Each fruiting head bears numerous elongate fruits with five persistent epigynous sepals and a single style with two stigmatic arms. The stamens have globose anthers with normal slitlike dehiscence and contain prolate tricolporate pollen with microreticulate ornamentation. Although the infructescences and fruits resemble those of extant Camptotheca, Browniea is distinguished by distinct calyx lobes, more elongate germination valves, normally dehiscing anthers, smaller pollen, and leaves that are consistently serrate. These fossils, together with those of Amersinia, Cornus, and Davidia, indicate that the Cornales were an important component of midlatitude North American Paleocene vegetation. ISSN: 0361-5995
Abstract: Ideal nitrogen (N) management for turfgrass supplies sufficient N for high-quality turf without increasing N leaching losses. A greenhouse study was conducted during two 27-wk periods to determine if in situ anion exchange membranes (AEMs) could predict nitrate (NO<inf>3</inf>-N) leaching from a Kentucky bluegrass (Poa pratensis L.) turf grown on intact soil columns. Treatments consisted of 16 rates of N fertilization, from 0 to 98 kg N ha ⁻¹ mo⁻¹. Percolate water was collected weekly and analyzed for NO<inf>3</inf>-N. Mean flow-weighted NO<inf>3</inf>-N concentration and cumulative mass in percolate were exponentially related (pseudo-R² = 0.995 and 0.994, respectively)

to AEM desorbed soil NO<inf>3</inf>-N, with a percolate concentration below 10 mg NO<inf>3</inf>-N L⁻¹ corresponding to an AEM soil NO<inf>3</inf>-N value of 2.9 (mu)g cm⁻² d⁻¹. Apparent N recovery by turf ranged from 28 to 40% of applied N, with a maximum corresponding to 4.7 (mu)g cm⁻² d⁻¹ AEM soil NO<inf>3</inf>-N. Turf color, growth, and chlorophyll index increased with increasing AEM soil NO<inf>3</inf>-N, but these increases occurred at the expense of increases in NO<inf>3</inf>-N leaching losses. These results suggest that AEMs might serve as a tool for predicting NO<inf>3</inf>-N leaching losses from turf. (copyright) Soil Science Society of America.

Abstract: The composition of root-zone solution of container grown Viburnum tinus L. 'Eve Price', Nerium oleander L. 'E(acute)mile Shaut' and Euonymus japonicus Thunb. were studied in two different localities (France and Spain). The growing media assayed were binary mixtures prepared with Finnish sphagnum peat, the following peat-substitutes: cattle manure compost, forest waste compost, pine bark compost, yard compost and raw coir. Perlite was used as inorganic amendment in one mixture. The composition of the root-zone solution was monitored by the induced percolate (IP) method and the applied nutrient solution (NS) was modulated by dilution in the experiments carried out in the French location or by increasing the volume applied to manage the electrical conductivity in the experiments conducted in the Spanish location. Modulation of the NS-water ratio resulted in a linear relation of percolate composition to NS composition. That relation was not present when the NS was not diluted. The results indicate that a steady-state nutrient level in the root zone can be achieved when a modulated and relatively low concentration of NS is applied by fertigation. Release of nutrients, especially nitrates, occurs during growing period. The biostability of the substrates and the initial availability of phosphorus and potassium determine the composition of the leachates. The results proved that the IP method can be used to monitor nutrient levels in the root zone and its use can enhance the nutrient-use efficiency in commercial nurseries. <u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: NO TOX DATA.

The Campo de Dalias, located between the central and eastern Betic Cordilleras, shows an evolution determined by the overprinting of two main stress fields since Pliocene times. The first of these develops hybrid and tensional joint sets up to Pleistocene (100 000 yr) and is characterized by NNW-SSE horizontal trend of compression and an ENE-WSW horizontal extension. The second stress field has prolate to triaxial extensional ellipsoids, also with ENE-WSW horizontal extension, and continues to be active today. The most recent stresses produce the reactivation of previous joints as faults whose trends are comprised mainly from N120[degree sign]E to N170[degree sign]E and have a normal and transtensional regime, with dextral or sinistral components. The palaeostress evolution of this region is similar to that undergone by other basins of the Eastern Betic Cordilleras, although the Pliocene-Pleistocene transcurrent deformations in the Campo de Dalias only develop joints and not strike-slip faults. ABSTRACT: Deinking by-products from paper recycling have been used as cover materials on acid-producing tailings. Due to residual cellulose, anaerobic degradation leads to the production of an organic-rich leachate, which may percolate through the tailings. This study aims at describing the influence of the tailings' characteristics on the attenuation of organic matter in leachate and at discussing the degradation mechanisms. To this end, leachate was mixed with different types of tailings, including three unoxidized tailings with varying acid generation potentials and one tailing in three states of oxidation. Regularly, selected biochemical parameters were analyzed to access the evolution of organic components. The results show that when leachate from deinking by-products was placed in contact with tailings, phase and acid-base balance reactions took place in the beginning. Subsequently, oxidation-reduction reactions dominated the chemistry of the system. The type, the constituents, and the state of oxidation of the mine tailings condition the mechanisms of biodegradation of organic components. Methanogenesis was predominant in the control sample (pure organic leachate) but was absent in all leachate-tailings mixtures. No biodegradation was observed in the liquid phase for oxidized tailings and the organic concentration remained constant for unoxidized tailings, independently of the acid-generation potential. The biodegradation efficiency was optimal when the leachate was in contact with a mixture of oxidized and unoxidized tailings due to sulfate-reduction.

The cytogenetic damage assocd. with exposure to mixts. of pesticides was evaluated by comparing peripheral blood lymphocyte micronucleus (MN) frequencies in a group of 64 female agricultural workers and 30 female controls. The exposed subjects worked during the spring and summer in thinning and pruning fruit trees and in harvesting and packing different fruits, such as raspberries, grapes, apples, and kiwis. They did not use any protective measures during their work activities. A significant increase in the frequency of binucleated cells with micronuclei (BNMN) was found in the exposed women as compared with the controls (36.94 +- 14.47 vs. 9.93 +- 6.17 BNMN/1000 BN cells; $P < 0.001$). The frequency of BNMN varied as a function of age in both the exposed and control groups, but no correlation was found between BNMN frequency and the duration of exposure. Also, smoking and other habits had no effect on MN frequency. Our study confirms that occupational exposure to pesticide mixts. results in cytogenetic damage. 835. Marshall, I. A. and Mitchell, J. P. (1992). The behaviour of spheroidal particles in time-of-flight aerodynamic particle sizers. *Journal of Aerosol Science* 23: 297-300.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Previous studies (Marshall , 1991; Marshall and Mitchell, 1991) have shown that time-of-flight aerodynamic particle sizers, such as the TSI Aerodynamic Particle Sizer and the Amherst Process Instruments Aerosizer, underestimate the aerodynamic size of cubeshaped particles, since they operate under ultra-Stokesian flow conditions. The present work has extended the investigation to include an assessment of the behaviour of two sizes of monodisperse, prolate spheroidal, ferric oxide particles close to 2 [mu]m aerodynamic diameter in both instruments. Both techniques undersized the smaller particles significantly, but the larger particles (more elongated) were oversized by the Aerodynamic Particle Sizer and undersized marginally by the Aerosizer. Similar behaviour was reported by Griffiths ., (1984) with micron-sized glass fibres sampled by an earlier version of the Aerodynamic Particle Sizer. Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. The SOLEPUR process for the treatment of pig slurry, based on the treatment effect of the soil, was developed in France to explore the notion that a simple biobarrier approach may be a potential efficient solution to the large accumulation of liquid animal wastes residues. The unit consists of (i) a managed field (3280 m2) which allows the total recovery of all the leachate water which percolates through growing ryegrass (Lolium perenne), to which the pig slurry is applied, (ii) a system of storage-pump-reactor for denitrification and (iii) a non-managed field for completing treatment. The process involves three operations: (1) overdosing the managed field with surplus slurry (about 1000 m3 pig slurry/ha.year applied from 1991 to 1994), (2) collecting and treating the nitrate-rich leachate and (3) irrigating the final treated water over other fields. This process decreased COD of pig slurry by 99.9% and removed 99.9% of phosphorus and approximately 80% of nitrogen. The

837. Martinez, M. Carmen Lopez and de La Torre, Jose Garcia (1983). Transport properties of rigid, symmetrical oligomeric structures composed of prolate, ellipsoidal subunits. *Biophysical Chemistry* 18: 269-279.
Chem Codes: Chemical of Concern: PSM Rejection Code: MODELING.

We have calculated translational and rotational diffusion coefficients and intrinsic viscosities of oligomeric structures composed of n identical subunits having a prolate ellipsoidal shape with axial ratio p. Results are presented for p = 1-6 for a variety of structures with n = 1-6. We compare our results with those obtained by a different modeling procedure, proposed by other workers, in which the monomeric subunit is represented as a string of touching, colinear spheres. If n and an estimate of p are known, the structure of the oligomer can be. in most cases, unambiguously determined by comparison of the experimental oligomer-to-monorner ratios of a given property with the numerical results of this work. As examples of the applicability of our results, we examine the relationship between structure and properties for neurophysin. bovine serum albumin, hemoglobin and phycocyanin. Diffusion/ Intrinsic viscosity/ Oligomeric structure/ Neurophysin/ Hemoglobin: Bovine serum albumin/ Phycocyanin

A new multiresidue method has been validated in cucumber matrix for the routine anal. of 130 multiclass pesticide residues by gas chromatog./triple quadrupole mass spectrometry. The pesticides were extd. with Et acetate. A first identification of the pesticides was based on a tandem mass spectrometric (MS/MS) screening method, which monitors a single transition for each target compd., in less than 12 min. After that, potentially non-neg. samples were analyzed again by the MS/MS confirmation/quantification

method, which monitors two or three MS/MS transitions for each compd., also in less than 12 min. Performance characteristics, such as trueness, precision, linear range, detection limit (LOD) and quantification limit (LOQ), for each pesticide were calcd. The av. recoveries obtained ranged between 70 and 120% at three different fortification levels (25, 200 and 500 mg/kg) with precision, expressed as relative std. deviation (RSD), values lower than 15%. The calcd. LOD and LOQ were typically <3.2 and 9.6 mg/kg, resp. Such limits were much lower than the max. residue levels (MRLs) established by European legislation. The proposed methodol. was applied to the detn. of pesticides in real vegetable samples from Almeria (Spain). [on SciFinder (R)] 0951-4198

<u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: CHEM METHODS.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. The paper describes a new sensitive and selective thin layer chromatographic method for the detection of some organophosphorous pesticides. Fifteen organophosphorous pesticides have been separated on thin layer using different stationary phases prepared at the "Raluca Ripan" Institute of Chemistry Cluj-Napoca, Roumania (silica gel R, amino bonded silica gel R) and some mixtures with different polarities as mobile phase (petroleum ether + chloroform + ethyl acetate 65:30:5, v/v). The detection was performed by spraying the TLC plates with a 9-methylacridine solution (0.05%) in ethanol and their examination under UV light at 366 nm. The spots present different colors and intensities. Detection limit is between 0.1 10 mug/spot.

Patent Application Country: Application: WO
Priority Application Country: US
Priority Application Number: 2005-724313
Priority Application Date: 20051006 Novel metal org. framework (MOF) mols. and methods of synthesizing them are described. MOFs are organometallic cryst. structures that have high sorption capacity due to high surface area, tailorable selectivity, an inert nature, and thermal stability at high temps. MOFs may be used as sorbents in preconcentrators for anal. devices to provide orders of magnitude of improved sensitivity in analyte detection. MOFs are also useful as sorbents in new compact and portable micropreconcentrator designs such as a modified purge and trap system and a multi-valve microelectromech. system (MEMS) to achieve high gain in analyte detection. Further, MOFs may be used as coatings for novel microstructure arrays in micropreconcentrators where the microstructures are designed to increase the surface area to vol. ratio inside the micropreconcentrator while minimizing the pressure drop across the micropreconcentrator. (GC) anal. of 15 organophosphorus pesticides commonly occurring in food crops was performed using the Thermedics Detection EZ Flash upgrade kit installed in the oven of a HP 5890 Series II Plus gas chromatograph. The temp. program and splitless time period were the main parameters to be optimized. In the first set of expts., wheat matrix-matched stds. were analyzed both by: (i) the flash GC technique (resistive heating of a 5 m capillary column), and (ii) the conventional GC technique (moderate oven temp. programming of a 30 m capillary column). Using the flash GC technique, the anal. time was reduced by a factor of more than 10 compared to the conventional GC technique. Dramatically improved detectability of analytes was achieved due to much narrower peak widths. The flash GC technique was compared with another approach to faster GC anal. employing a 5 m column and fast temp. programming with a conventional GC oven. In comparison with this alternative, in the case of flash GC significantly better retention time repeatability was obsd. The other superiority of resistive heating is very rapid cooling down (i.e., equilibration to the initial conditions) which contributes to the increased sample throughput. Citations: 32) Mastovska, K; Anal Chem, manuscript in preparation Low-pressure gas chromatog.-mass spectrometry (LP-GC-MS) using a quadrupole MS instrument was further optimized and evaluated for the fast anal. of multiple pesticide residues in food crops. Performance of two different LP-GC-MS column configurations was compared in various expts., including ruggedness tests with repeated injections of pesticides in matrix exts. The tested column configurations employed the same 3 m * 0.15 mm i.d. restriction capillary at the inlet end, but

different anal. columns attached to the vacuum: (A) a 10 m * 0.53 mm i.d., 1 mm film thickness RTX-5 Sil MS column; and (B) a 10 m * 0.25 mm i.d., 0.25 mm film thickness DB-5MS column. Under the optimized conditions (compromise between speed and sensitivity), the narrower anal. column with a thinner film provided slightly (<1.1-fold) faster anal. of <5.5 min sepn. times and somewhat greater sepn. efficiency. However, lower detection limits for most of the tested pesticides in real exts. were achieved using the mega-bore configuration, which also provided significantly greater ruggedness of the anal. (long-term repeatability of analyte peak intensities, shapes, and retention times). Addnl., the effect of the increasing injection vol. (1-5 ml) on analyte signal-to-noise ratios was evaluated. For the majority of the tested analyte-matrix combinations, the increase in sensitivity caused by a larger injection did not translate in the same gain in analyte detectability. Considering the costs and benefits, the injection vol. of 2-3 ml was optimal for detectability of the majority of 57 selected pesticides in apple, carrot, lettuce, and wheat exts. 844. Matsuzaki, Shigenobu, Inoue, Tetsuyoshi, Kuroda, Masayuki, Kimura, Susumu, and Tanaka, Shuji (1998). Cloning and sequencing of major capsid protein (mcp) gene of a vibriophage, KVP20, possibly related to T-even coliphages. *Gene* 222: 25-30.
Chem Codes: Chemical of Concern: PSM Rejection Code: VIRUS.

A large, tailed, prolate-headed vibriophage designated KVP20 was isolated from seawater. KVP20 was morphologically very similar to the previously described vibriophage, KVP40 (Matsuzaki, S., Inoue, T., Tanaka, S., 1998. Virology, 242, 314-318). However, they showed entirely different host specificities and could easily be differentiated from each other by their patterns of DNA restriction fragments. The major capsid protein (mcp) gene of KVP20 encoding the precursor of major capsid protein (pro-Mcp) was cloned and sequenced. The deduced amino-acid (aa) sequence of KVP20 pro-Mcp was compared with the reported aa sequences of KVP40 pro-Mcp, as well as of the equivalent proteins (gp23s) of coliphages T4 and RB49. There was 96.7, 57.5, and 55.2% homology to the corresponding proteins of KVP40, T4, and RB49, respectively. These data strongly suggest that the two vibriophages are closely related to each other and that they are both distantly, but definitely, related to coliphages T4 and RB49. (detn. of, in fruits and vegetables by gas chromatog.-mass spectrometry) Apple, peach, tomato, and potato (25 samples each) were analyzed for 12 pesticides and 2 pesticide metabolites with a slightly modified Luke multiresidue extn. procedure (1), sepn. by capillary column (DB-1 Me silicone fused silica) gas chromatog. with cold on-column injection and temp. programming (50-300 Deg at 15 Deg/min), and detection by mass chromatog. with an ion trap mass spectrometer in the chem. ionization mode (GC/CIMS). Residues of carbaryl, captan, dichloran, dimethoate, methamidophos, phosmet, and tetrahydrophthalimide were found in several samples, with peaches contg. the most residues. None of the residues was above legal tolerances. Recovery studies at the 0.5 ppm fortification level of each pesticide and metabolite in each of the crops indicated recoveries of 73-120%, with an av. relative std. deviation of 11%. Because the computer can be programmed to search for several hundred targeted ions, the use of capillary column GC/CIMS is a promising method that should be explored by regulatory agencies for the anal. of pesticide residues. CAS Registry Numbers: 52645-53-1; 52918-63-5 Role: BIOL (Biological study) (acaricidal formulations contg. organophosphorus compds. and); 78-34-2; 141-66-2; 333-41-5; 470-90-6; 563-12-2; 732-11-6; 786-19-6; 1776-83-6; 2921-88-2; 4824-78-6; 7700-17-6; 16759-59-4 Role: BIOL (Biological study) (acaricidal formulations contg. pyrethroids and)
Patent Application Country: Application: AU The activity of organophosphorus pesticides, e.g., bromophos-ethyl [4824-78-6] and chlorpyrifos [2921-88-2], against ectoparasites of the suborders Ixodoidea and Sarcoptiformes was potentiated by adding a pyrethroid of the formula I (X = H or CN). Thus, mixts. of permethrin [52645-53-1] and bromophos-Et, chlorpyrifos, diazinon [333-41-5], dioxathion [78-34-2], ethion [563-12-2], dicrotophos [141-66-2] or chlorfenvinphos [470-90-6] at ratios 1:1, 1:5, and 5:1 were more effective against Boophilus microplus than each component alone. Decamethrin [52918-63-5] mixts. with the above organophosphorus insecticides showed the same trend as permethrin. Different formulations (miscible-oil, dusting powder, wettable powder, pressure-pack) of I and organophosphorus pesticides are described. A 99.9% control of B. microplus was obtained with a mixt. of 500 ppm ethion and 100 ppm permethrin. 847. Max Finlayson, C. and Chick, Alan J. (1983). Testing the potential of aquatic plants to treat abattoir effluent. *Water Research* 17: 415-422.
Chem Codes: Chemical of Concern: PSM Rejection Code: EFFLUENT, FATE.

The potential of 3 genera of emergent aquatic plant species (Typha spp, Phragmites and Scirpus) to ameliorate effluent from a poultry abattoir was evaluated in an experimental trench system. Three plastic-lined trenches containing Typha (two species), Phragmites and Scirpus plants in a

gravel substrate were constructed near the abattoir. Effluent was allowed to percolate, with retention times of 2.7-3.6 days, through the trenches. The quality of the inflowing and outflowing effluent was compared by a regular sampling program for suspended solids, conductivity, turbidity, pH, dissolved oxygen, Na, K, Cl, N and P concentrations. The importance of water loss by evapotranspiration was investigated. Comparing the inflow to outflow, each trench system successfully reduced the suspended solids (83-89%), turbidity (58-67%), total nitrogen (14-56%) and total phosphorus (37-61%) concentration of the effluent while maintaining an acceptable pH and in the case of the Phragmites and Scirpus systems oxygenating the anaerobic inflow. Conductivity increased in the Typha and Phragmites trenches. If a correction is made for water lost by evapotranspiration, the three experimental trench systems reduced the nitrogen (42-75%), phosphorus (68-79%), sodium (7-34%), potassium (9-56%) content of the effluent. The chloride content of the effluent in the Phragmites system was increased by 15% but was reduced by 31 and 53% in the Typha and Scirpus systems respectively. The results from this initial experiment give an indication of the relative abilities of the three plant systems to treat the wastewater from the abattoir. Of the three, that containing the Scirpus was superior.

848. Maxey, George B. and Hackett, James E. (1963). Applications of geohydrologic concepts in geology. *Journal of Hydrology* 1: 35-45.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

Subsurface water, an active agent in many geologic proceses, must be considered in interpreting geologic phenomena. Principles of the occurrence, distribution, and movement of subsurface waters are well established and readily applicable. In many interpretations in geologic literature, geohydrologic principles have been employed realistically, but in many others these principles have been either ignored or violated. Explanations of genesis of underclays and associated deposits afford some examples wherein principles of movement and activity of vadose and ground water have been ignored and others in which they have been used advantageously. Postulates stating that waters percolate downward from swamp areas do not allow for the usual movement of subsurface water in such environments. The idea that sediments were leached by vadose water after uplift satisfies the geohydrologic requirements. Weathering and solution form porous and permeable zones subjacent to unconformities in dense rocks such as carbonates and granites; this illustrates the geohydrologic and economic significance of unconformities. Examples are Mohawkian carbonate aquifers of northern Illinois and oil-bearing limestones of Mississippian age of eastern Montana. The flushing effects of meteoric water and other hydrodynamic factors active during erosion periods are important elements in the genesis and concentration of brines. Explanation of the origin and occurrence of brines must include consideration of the geohydrologic environments throughout their geologic history.

ISSN: 0036-1488
Abstract: A new species of Buddlejaceae, Emorya rinconensis, is described here as the second species of the genus. The species is known from a single collection from the Serranias del Burro in northern Coahuila, Mexico. Although associated with a more mesic flora than Emorya suaveolens,

morphological adaptations and associated species suggest that E. rinconensis may grow in edaphically xeric, steep rock outcrops. The racemose inflorescences of the new species are unique among New World Buddlejaceae and appear to represent a reduction from the open, few-flowered axillary cymes found in Emorya suaveolens. In the context of North American Buddlejaceae, the long tubular corollas in open inflorescences, long styles, linear calyx lobes, and prolate pollen support the present generic placement of the new species with Emorya, but future confirmation of the phyletic position of both species in a larger geographic context is needed.

A community-based approach to implement culturally appropriate research methods with a migrant Latino farmworker community in Oregon is described. Assessments were conducted in 96 farmworker homes and 24 grower homes in 2 agricultural communities in Oregon. Measurements included surveys of pesticide use and work protection practices and analyses of home-dust samples for pesticide residues of major organophosphates used in area crops. Results indicate that migrant farmworker housing is diverse, and the amts. and types of pesticide residues found in homes differ. Azinphos-Me (AZM) was the pesticide residue found most often in both farmworker and grower homes. The median level of AZM in farmworker homes was 1.45 ppm compared to 1.64 ppm in the entry area of grower homes. The median level of AZM in the play areas of grower homes was 0.71 ppm. The levels of AZM in migrant farmworker homes were most assocd. with the distance from fields and the no. of agricultural workers in the home. Although the levels of AZM in growers and farmworker homes were comparable in certain areas, potential for disproportionate exposures occur in areas of the homes where children are most likely to play. The relationship between home resident d., levels of pesticide residues, and play behaviors of children merit further attention. 853. Mccully, L. A. (Report on Organophosphorus Pesticides.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: PESTAB. Various reports on organophosphorus pesticide residue analysis techniques are presented in a brief summary. A method for ethoprop residues by gas-liquid chromatography (GLC) with flame photometric detection is described. Residue methodology using GLC for fenamiphos and fensulfothion in tobacco is also given. A polarographic technique for phosmet in apples is reported. A technique to simultaneously determine residues of vamidothion, its sulfoxide, and its sulfone in tobacco has been developed. A GLC method applicable to 40 organophosphorus pesticide residues in plant material is described. Other GLC techniques are described for the determination of organophosphorus compounds in such substrates as Chinese cabbage, foods, organic soils, and other fruits and vegetables are given. Confirmation procedures are discussed for various pesticide residues in water. Results of studies involving the sweep codistillation technique are reported. Specific reports are still needed on such topics as chlorine-containing organophosphorus pesticides, extraction procedures, soil, and water. [At the 92nd annual meeting of the Association of Official Analytical Chemists.]

samples together with output from the CalTOX multi-media, multi-pathway, source-to-dose model. The study population was the CHAMACOS cohort of almost 600 pregnant Latina women in the Salinas Valley region. Model ests. of OP intake and urinary dialkylphosphate (DAP) metabolite excretion were used to develop premises about relative contributions from different exposure sources and pathways. These premises were evaluated by comparing the magnitude and variation of DAP in the CHAMACOS cohort with those of the entire US population using National Health and Nutrition Examn. Survey (NHANES) data. This comparison supported the premise that diet was the common, dominant exposure pathway in both populations. Biomarker comparisons and model results supported the observation that, relative to NHANES, the CHAMACOS population had a statistically significant ($p < 0.001$) added OP pesticide intake with low inter-individual variability. The magnitude and small variance of this intake was attributed to residential, non-dietary exposure from local agricultural OP uses. Results showed mass balance models can est. OP pesticide exposure within the range measured by biomonitoring. Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. The leukotoxin (LktA) from Pasteurella haemolytica and the hemolysin (AppA) from Actinobacillus pleuropneumoniae are members of a highly conserved family of cytolytic proteins by gram-negative bacteria. Despite the extensive homology between these gene products, LktA is specific for ruminant leukocytes while AppA, like other hemolysins, lyses erythrocytes and a variety of nucleated cells, including ruminant leukocytes. Both proteins require activation facilitate by the product of an accessory re toxins by recombining domains to ltkA and appA and have examined the target cell specificities of the resulting hybrid proteins. Our results indicate that the leukocytic potential of AppA, like that of LktA, maps to the C-terminal half of the protein and is physically separable from the region specifying erythrocytes lysis. As a consequence, we were able to construct an RTX toxin capable of lysing erythrocytes but not leukocytes. The specificity of one hybrid was found to be depe

Index Terms: Soils (Imidan decompn. in)
CAS Registry Numbers: 732-11-6 (Phosphorodithioic acid, O,O-dimethyl ester S-ester with N-(mercaptomethyl)phthalimide) (decompn. in soil) The disappearance rate of Imidan was studied in a sandy loam and a loam soil. The effect of soil compn., moisture, pH, and microorganisms on persistence was also evaluated. Residues of Imidan and its thiol analog, Imidoxon, were detd. according to a phosphomolybdate colorimetric method. Imidan degraded very rapidly in both soils. The time for 50% degradation in a sandy loam soil and a loamy soil was in the range of 3-19 days. The major factor assocd. with degradation of Imidan in soils appears to be spontaneous hydrolysis. Chem Codes: Chemical of Concern: PSM Rejection Code: SURVEY.

ISSN: 0556-3321
Abstract: Pollen morphological characters of 5 species of Scorzonera have been investigated from Pakistan by light microscopy. Pollen grains are usually radially symmetrical, isopolar, prolate-spheroidal in equatorial view, semi-angular to inter-semi-angular in polar view, trizonocolporate, non-lacunate and echinate. Pollen characters such as size, shape, colpi and exine thickness, and aperture type are found considerably important. Scorzonera hondae can be distinguished due to its sub-prolate shape whereas S. picridioides has oblate-spheroidal subprolate P/E ratio (0.95). The pollen spine character is a diagnostic character in this genus. S. hondae has the highest spine length (4.8 (mu)m) and S. laciniata can be distinguished due to lowest spine length 2.5 (mu)m. There is a great range of variation in exine thickness which has proved useful at specific level. On the basis of exine thickness 3 groups viz. Group I: S. virgata, S. laciniata, Group II: S. picridioides, Group III: S. ammophila, S. hondae are recognized.

863. Mercade, Josep V. and Montoya, Angel (1997). A monoclonal antibody-based ELISA for the analysis of azinphos-methyl in fruit juices: The Second Workshop on Biosensors and Bioanalytical Techniques in Environmental Analysis. *Analytica Chimica Acta* 347: 95-101.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

A monoclonal antibody-based enzyme-linked immunosorbent assay (ELISA) was developed for the quantification of azinphos-methyl . The competitive ELISA was performed in the antibody-coated format using a homologous peroxidase-hapten conjugate as enzyme tracer. For standards, the I50 value of the ELISA was around 3 ng ml-1 with a detection limit of 0.4 ng ml-1. On the basis of previous crossreactivity studies, multianalyte standards containing the three pesticides recognized by the antibody (azinphos-methyl, azinphos-ethyl, and phosmet) were assayed. Results

showed that the total content of these analytes can be accurately determined using a unique azinphos-methyl standard curve, as long as the three compounds are in equimolar amounts. The suitability of the ELISA for pesticide quantification in orange and apple juices was also studied. The practical detection limit in juice samples was 100 ng ml-1. Therefore, samples were spiked with azinphos-methyl in the 100-1000 ng ml-1 range and directly analyzed without any pretreatment other than a 1/100 dilution in PBS to minimize matrix effects. Under these conditions, good accuracy and precision were obtained, with mean recoveries of 122.7% and 110.5%, and mean coefficients of variation of 14.5% and 15.1%, for orange and apple juices, respectively. No false positives were found. Azinphos-methyl/ Azinphos-ethyl/ Phosmet/ Immunoassay/ Pesticide/ Insecticide/ Food analysis

A panel of haptens was synthesized for immunoconjugate prepn., and a series of haptens for heterologous, coating or tracer, conjugates was also prepd. Hapten synthesis was based on a strategy in which only a fragment of the whole target mol. was present (fragmentary haptens). From immunized mice, a set of monoclonal antibodies was obtained and ELISA sensitivities were assayed in different formats. Affinities estd. as I50 values in the low nanomolar range for azinphos-Me and phosmet were obsd. for several monoclonal antibodies in the conjugate-coated format and in the antibody-coated format under nonoptimized assay conditions. Citations: Wortberg, M; J Agric Food Chem 1996, 44, 2210 Two ELISAs for azinphos-Me have been optimized and characterized. Both ELISAs are based on monoclonal antibodies produced from an immunogen with a hapten contg. a phthalimido moiety and on protein conjugates of heterologous ligands contg. a 1,2,3-benzotriazine group. Assay I was performed in the conjugate-coated ELISA format and assay II in the antibody-coated format. Several physicochem. factors (ionic strength, pH, incubation times, and Tween 20 and BSA concns.) that influence assay performance were studied and optimized. Both monoclonal immunoassays highly cross-reacted with azinphos-Et and phosmet. Both assays were applied to the anal. of azinphos-Me in spiked real water samples. For assay I the sensitivity, estd. as the I50 value, was 0.40 nM, with a practical working range between 0.10 and 1.75 ng/mL and a limit of detection of 0.05 ng/mL. For assay II the sensitivity was 1.01 nM, with a practical working range between 0.32 and 2.54 ng/mL and a limit of detection of 0.08 ng/mL. With this aim, the authors synthesized a hapten consisting of only the arom. moiety of the pesticide attached to a spacer arm and terminated by a carboxylic function. This simple strategy keeps the main groups that are characteristic of azinphos, and it can presumably be applied to other organophosphorus pesticides. The immunization of mice with a protein conjugate of this hapten allowed us to obtain several monoclonal antibodies to azinphos-Me. By homologous, competitive indirect ELISA, monoclonal antibodies LIB/MBP-3.1 and LIB/MBP-3.4 showed an I50 of 346 nM (100 mg/L) and 28 nM (9 mg/L), resp., for azinphos-Me. Cross-reactivity studies demonstrated that both antibodies also recognized azinphos-Et. LIB/MBP-3.1 also had some cross-reactivity with quinalphos and phosmet, and LIB/MBP-3.4 recognized phosmet as well as azinphos-Me. Chem Codes: Chemical of Concern: PSM Rejection Code: NO TOXICANT.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Anystis wallacei preferred redlegged earth mite and Neomulgus capillatus preferred lucerne flea in the insectary. Feeding tests showed that 100 A. wallacei per square metre can kill 16,000 redlegged earth mites in one pest generation. Two types of field trials were conducted using a novel barrier system. The addition of both predators into ungrazed plots reduced peak pest numbers by more than two thirds, while vegetative and seed yields were more than doubled. Pest numbers were low in mown plots but peak populations of redlegged earth mite and lucerne flea were reduced by 80 and 60% respectively. A. wallacei was reared in field cages for two years at greater densities than naturally occurring in the field. Predators survived in much greater numbers than pests after sprays of common pesticides.

ISSN: 1351-0754
Abstract: Dissolved organic nitrogen and carbon (DEC) are significant in the C and N cycle in terrestrial ecosystems. Little is known about their dynamics in the field and the factors regulating their concentrations and fluxes. We followed the fluxes and concentrations of the two in a Norway spruce (Picea abies (L.) Karst.) forest ecosystem in Germany from 1995 to 1997 by sampling at fortnightly intervals. Bulk precipitation, throughfall, forest floor percolates from different horizons and soil solutions from different depths were analysed for major ions, dissolved organic N and Dec. The largest fluxes and concentrations were observed in percolates of the Oi layer, which contain amine N and amine sugar N as the major components. The average ratio of dissolved organic C to N in forest floor percolates corresponded to the C/N ratio of the solid phase. Concentrations and fluxes were highly dynamic with time and decreased with depth. The largest fluxes in forest floor percolates occurred when the snow melted. The concentrations and fluxes of dissolved organic N were significantly correlated with DOC, but the correlation was weak, indicating different mechanisms of release and consumption. The dynamics of dissolved organic N and Dec in forest floor percolates were not explained by pH and ionic strength of the soil solution nor by the water flux, despite large variations in these. Furthermore, the release of these fractions from the forest floor was not related to the quality and amount of throughfall. Concentrations of dissolved organic N in forest floor percolates increased with soil temperature, while temperature effects on Dec were less pronounced, but their fluxes from the forest floor were not correlated with temperature. In the growing season concentrations of both dissolved organic N and C in forest floor percolates decreased with increasing intensity of throughfall. Thus, the average throughfall intensity was more important than the amount of percolate in regulating their concentrations in forest floor percolates. Our data emphasize the role of dissolved organic N and Dec in the N and C cycle of forest ecosystems.

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: TD3: In recent years it has become increasingly evident that numerous aquifers have become contaminated as a result of leaks from storage tanks and accidental spills of gasoline, aviation fuel, chlorinated solvents, and other organic liquids having low solubilities in water. Accordingly, it is important to develop a basic understanding of how an organic liquid (hereafter called oil for simplicity), which is largely immiscible with water, percolates through the soil until it reaches the water table and, in situations where its density is less than water, spreads there. Similarity solutions are developed for gravity-dominated spreading at the water table of a lens of organic liquid largely immiscible with water. Different solutions deal with different mechanisms by which the lens volume decreases with time: dissolution or evaporation, trapping as water invades the region beneath the central part of the lens, and uniform degradation. In the last case, the solution is a special case of the Barenblatt-Pat

Poisoning of Raptors With Organophosphorus and Carbamate Pesticides With Emphasis on Canada, U.s. And U.k. *Journal of raptor research* 33: 1-37.
Chem Codes: Chemical of Concern: PSM Rejection Code: REVIEW.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. We reviewed cases of raptor mortality resulting from cholinesterase-inhibiting pesticides. We compiled records from the U.S., U.K. and Canada for the period 1985-95 (520 incidents) and surveyed the relevant literature to identify the main routes of exposure and those products that led to the greatest number of poisoning cases. A high proportion of cases in the U.K. resulted from abusive uses of pesticides (willful poisoning). The proportion was smaller in North America where problems with labele nophosphorus products as avicides and for the topical treatment of livestock appeared to be common routes of intoxication. The use of insecticides in dormant oils also gave rise to exposure that can be lethal or which can debilitate birds and increase their vulnerability. A few pesticides of high toxicity were responsible for the bulk of poisoning cases. Based on limited information, raptors appeared to be more sensitive than other bird species to organophosphorus and carbamate p

875. Mirkhaitov, T. and Ikramov, L. T. (Determination of the Phosalone and Phthalophos in the Forensic-Chemical Analysis of Biological Materials. *Farmatsiya22(6): 64-67* 1973.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: PESTAB Methods are described for the detection and quantitative determination of phosalone and phthalophos phosmet in biological materials for forensic analyses. Extraction from the homogenized samples is best done by means of ether at pH 5. The rates of recovery after three subsequent extractions are 41% for phthalophos and 48% for phosalone. For qualitative determination the samples are transferred in benzene and cleaned on alumina and silica gel layer, after which identification is possible on KSK silica gel layer by means of bromphenol blue with acetone and silver nitrate, and of acetic acid. For quantitative determination, the dehydrated samples are mineralized by means of concentrated nitric and sulfuric acids, after which phthalophos is determined by means of alcoholic saturated solution of silver nitrate, mercury dibromide, or mercury diiodide. Phosalone is determined by means of alcoholic solution of silver nitrate, mercury dichloride, or mercury diiodide. The limit of the chromatographic detection amounts to 20 mug per 100 g for phosalone and to 30 mug per 100 g for phthalophos. The sensitivity of the quantitative determination is 1 mg for phosalone and 2 mg for phthalophos in 100 g biological material.

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: PESTAB. The extraction of phosalone and phthalophos from aqueous solutions for subsequent colorimetric determination by the phosphomolybdenum blue method was studied at different pH values. Phosalone was extracted with chloroform, dichloroethane, ethyl ether, n-butanol, benzene, and toluene from both acid and alkaline solutions. However, it was not extracted by petroleum ether. The rate of extraction was highest, with 85-95%, at pH 1-5, and 94% at pH 1. Petroleum ether was found to be best for the extraction of phthalophos. The rate of extraction was 95% at pH 1 and 12% at pH 11.

ABSTRACT: PESTAB. A method for the extraction, cleanup, identification, and quantitative determination of phosaline and phthalophos (phosmet) in biological materials as encountered in forensic practice is described. Threefold extraction with ether at pH 5 permits recovery of up to 41% of phthalophos and up to 48% of phosalone. The extract is transferred into benzene for chromatographic cleanup on alumina and silicagel. Following elution with benzene, the dry residue is dissolved in alcohol for chromatographic identification on a silicagel layer, using chloroform as a solvent, and bromophenol blue with acetic acid for the visualization of the tracer. Another part of the eluate is evaporated, and the dry residue is mineralized with concentrated nitric acid and sulfuric acid for the quantitative identification of phthalophos and phosalone by a photocolorimetric method on the basis of the formation of phosphomolybdic blue, or by other known methods. The sensitivity of the quantitative determination amounts to 1 mg for phosalone, and 2 mg for phthalophos in 100 g sample.

Several features of this assay make it attractive for development as a lab.-based or field screening assay. Acetylcholinesterase (AChE) was stabilized in a gelatin film. The remarkable properties of the

dry immobilized AChE prepn. include its stability to prolonged storage at room temp. as well as its stability to short-term elevated temps. (60 Deg). The enzyme could be maintained in dry gel form for 365 days at room temp. without substantial loss of activity. The absorbance assay used to measure enzyme activity was evaluated using several solvent systems including water, phosphate buffer, hexane, methanol, and ethanol. The microwell assay includes a procedure to oxidize less potent P=S organophosphorus compds. to their more inhibitory oxon forms. The use of this assay to analyze field samples contaminated with mixts. of organophosphorus insecticides is also reported. Chem Codes: Chemical of Concern: PSM Rejection Code: MODELING.

The left ventricle is modelled as a prolate spheroid of viscoelastic material with an aim to demonstrate the qualitative effects of anistropy and nonhomogeneity in the calculation of intact ventricular wall stresses. The pericardial pressure is accounted for in the analysis and an attempt is made to examine to what extent this influences the ventricular stresses. Numerical results are also obtained by computing the analytical expressions derived through the analysis.

Citations: 16) Wigfield, Y; Bull Environ Contam Toxicol 1994, 53, 543 A process for predicting the potential for persistence of agrochem. residue levels in beer has been developed. For this, anal. methods were first developed for detg. the agrochem. residues in beer, wort, and various byproducts during the brewing processes. Second, various types of agrochems. were spiked during the mashing, wort boiling, or fermn. processes and the residues in the product and in the byproduct were detd. with the developed method. Agrochems. added were representative of the

typical chem. groups of agrochems. for which max. residual levels in barley or hops are regulated by Japanese law. Third, the potential for the carryover of agrochem. residues into wort and beer was investigated based on chem. properties such as thermostability, chem. reactivity, and oil/water soly. (which was expressed as log Pow values). It was found that the carryover of agrochem. residues into wort and beer depended on their log Pow values. The carryover percentages into wort or beer of glyphosate (organophosphorus herbicide) having the lowest log Pow value were more than 90% of the amt. added to each process. On the other hand, most of the agrochems. having a high log Pow value, such as pyrethroid pesticides, were detected in the fractions of the spent grains and spent hops. Some amts. of the added agrochems. were lost during the wort boiling process. On the other hand, no significant redn. was obsd. during the fermn. process. None of the agrochems. spiked in the hop pellets were detected in beer because of the loss during boiling and fermn., though the levels of the spiked agrochems. were high enough to be detected in beer if no loss of the spiked agrochems. had occurred. From these results, the process for predicting the potential for the carryover of agrochem. residues in malt or hops into beer on a lab. scale was proposed, in that the log Pow values of a agrochem. was effectively used as the primary indicator. The pesticides investigated were diazinon, methyl parathion, chlorpyrifos, malathion, phosmet, and azinphosmethyl. These compds. are of interest due to their use in agricultural tree fruit prodn. and/or urban pest control. Pesticides were detd. via gas chromatog./mass spectrometry with selected-ion monitoring and cool on-column injection. The lower limit of method validation was 0.20 mg/g. Method limits of detection in dust ranged from 0.012-0.055 mg/g. Dust samples were collected with vacuums from the homes and vehicles of people living and working in a rural agricultural region in the central part of Washington State. The analytes were extd. from the dust by sonication in acetone. The exts. were solvent-exchanged to cyclohexane, frozen, thawed, and centrifuged prior to SEC injection. Following SEC, the eluent was split into 2 fractions, concd., and injected on-column into the gas chromatograph. This method represents the first complete publication describing the SEC cleanup of organophosphorus pesticides in dusts. Recoveries of pesticides in dusts ranged from 63.5-110.8 +-4.9-19.6% over a fortification range of 0.20-10.00 mg/g. This optimized, automated, and reproducible SEC method does not require further treatment or cleanup for trace detn. of these organophosphorus pesticides. <u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: BIOLOGICAL TOXICANT.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Natural leachates of Eucalyptus globulus (throughfall, stemflow, and soil percolates) were collected daily during rainy spells in the vegetative period (February-July), and their effects on the germination and radicle growth of Lactuca sativa were measured. Concurrently, the effects of L. sativa of topsoil and leachates from decaying litter were determined. The results suggest that toxic allelochemicals released by Eucalyptus globulus may influence the composition and structure of the understory of the plantation and that this effect is attributable mainly to the decomposition products of decaying litter rather than to aerial leachates. The soil may neutralize or dilute allelopathic agents, at least below the top few cms.

885. Montana*, Carlos, Cavagnaro+, Bruno, and Briones*++, Oscar (1995). Soil water use by co-existing shrubs and grasses in the Southern Chihuahuan Desert, Mexico. *Journal of Arid Environments* 31: 1-13.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

Soil water use by shrubs and grasses of vegetation patches (vegetation arcs) occurring in two-phase mosaics of the Southern Chihuahuan Desert (Mexico) was investigated after an experimental irrigation equivalent to a 75 mm rainfall. Three shrubs (Flourensia cernua,Larrea tridentataandProsopis glandulosa) and one grass (Hilaria mutica) were studied. Irrigation water did not percolate deeper than 40 cm. This soil layer contained more than 75% of the roots in all species, exceptP. glandulosawhere a less developed, deeper root system was detected (but not quantified). Root distribution indicates that the water stored in the 0-40-cm soil layer after the experimental irrigation was available for the four species. However, predawn xylem water potential (XWP) ofF. cernuaandH. muticawere strongly influenced by soil water present in the 0-40-cm layer, whereas those ofL. tridentataandP. glandulosawere not. Differences in predawn XWP between watered and unwatered individuals were greatest inF. cernuaandH. mutica, and smallest inP. glandulosa. Changes in tissue osmotic potential (TOP) values as a consequence of watering were sharply marked in all species exceptP. glandulosa. H. muticaXWP approached zero for a few days in response to small rain events. The results indicate that adult individuals of grasses and shrubs are potential competitors for soil resources (to a variable degree according to the shrub species). Their co-existence in the arcs is probably favoured by a process of slow competitive displacement as long as the recruitment of new shrubs takes place mainly by colonization of the upslope fringe of the arcs where grass biomass is low. As development of the vegetation progresses in the colonization front and the grass canopy is almost closed, the chances of a shrub being suppressed by water competition diminishes in the following order:F. cernua,L. tridentata,P. glandulosa. A drastic reduction in grass biomass because of grazing would depress the competitive ability of the grasses and may preferentially facilitate the establishment of livestock dispersed species likeP. glandulosa. A consequent shift to a more shrubby community seems unavoidable

since the recovery of the grass strata will probably not suppress the newly-established shrubs tapping water from deep water sources. Flourensia cernua; Larrea tridentata; Prosopis glandulosa; Hilaria mutica; Chihuahuan Desert; vegetation arcs; water use; colonization

Abstract: Agricultural systems of Argentina have increased herbicides inputs, mostly associated with adoption of no tillage (NT). Several studies have revealed presence of pesticides in groundwater. Therefore, research on the behaviour of herbicides in soils is driven by the need to manage and prevent possible contamination of groundwater. Soil organic carbon (OC) is the main soil component responsible of sorption, and consequently the main tool to reduce the leaching. However, in dynamic systems transport of organic chemicals depends on soil structural and hydraulic properties. Sorption controls the physical and biological availability of chemicals. Physical, heterogeneous flow domain, and chemical, kinetic reactions and molecular diffusion into aggregates, which are nonequilibrium processes that affect solute transport. The main objective of this paper was to evaluate the effects of soil texture and tillage system on atrazine transport through intact soil columns. The study focused on the identification of processes; and determination of parameters that control atrazine transport in the upper layer of soils. Balcarce (BAL, silty clay loam, fine, thermic, illitic, Typic Argiudoll)), Tres Arroyos (TAR, clay loam, fine, thermic, illitic, Typic Argiudoll) and Coronel Dorrego (DOR, loam, fine, thermic, mixed illitic-montmorillonitic, Typic Argiudoll) soils from the southeast of Buenos Aires Province (Argentina) were selected. The soils represent a wide range of OC content (BAL 35.5, TAR 28.8 and DOR 17.3[space]g kg^{- 1}). At each site NT and conventional tillage (CT) systems were sampled. Four replicates of intact soils cores (15 x 8[space]cm) were removed from each combination of soil x tillage (BAL-NT, BAL-CT, TAR-NT, TAR-CT, DOR-NT, DOR-CT). Displacement studies were done using atrazine as the reactive solute and bromide as the nonreactive solute. Equilibrium and nonequilibrium transport models (CXTFIT 2.1) were employed to describe the breakthrough curves (BTCs). The software tool SMART was used to simulate atrazine transport under steady-state flow conditions. Atrazine BTCs were skewed to the right; exhibiting an asymmetric shape and tailing that implied nonequilibrium conditions during transport. Since physical nonequilibrium was assumed to be nearly negligible, the observed nonequilibrium was interpreted as a sorption-related process. The two-site nonequilibrium model showed an acceptable fit with the observed data (72 < R² < 86). Recovery percentages of atrazine in effluents were: BAL-CT 54.51%; BAL-NT 45.10%; TAR-CT 44.28%; TAR-NT 29.70%; DOR-CT 18.60%; DOR-NT 48.95%. The intraparticle diffusion model provided by SMART showed the best fit. In conclusion, intrinsic soil properties were more relevant for atrazine transport than those associated with tillage practices. However, no tillage produced early detection of atrazine in effluents, and favoured atrazine leaching in coarser soils with the lowest OC contents. However, the maximum loss of atrazine in the percolate took place in the soils with the highest OC level; with no effects of tillage practices. These soils had fine texture, and were well structured and aggregated. Intraparticle and intraorganic matter diffusion appear to be responsible for nonequilibrium sorption. Delayed sorption in aggregated soils leads to high concentration of atrazine available for leaching. (copyright) 2006 Elsevier B.V. All rights reserved.

887. Moody, Michael F. (1999). Geometry of phage head construction. *Journal of Molecular Biology* 293: 401-433.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

The process of phage capsid assembly is reviewed, with particular attention to the probable role of curvature in helping to determine head size and shape. Both measures of curvature (mean curvature and Gaussian curvature, explained in), should act best when the assembling shell is spherical, which could account for procapsids having this shape. Procapsids are also relatively thick, which should help head size determination by the mean curvature. The accessory role of inner and outer scaffolds in size determination and head nucleation is also reviewed. Nucleation failure generates various malformations, including non-closure, but the most common is the tube or polyhead, where the subunits' inherent curvature is expressed as a constant mean curvature. This induces lattice distortions that only partly understood. An extra tubular section in normal heads leads to the prolate shape, with a more complex and variable geometry. Newly assembled procapsids are both enlarged and toughened by the head transformation. In the procapsid the Gaussian curvature is uniformly distributed. But toughening tends to equalize bond lengths, so all the Gaussian curvature gets concentrated in the vertices, being zero elsewhere. This explains head angularization. Because of this change in Gaussian curvature, the regular subunit packing in the polyhedral head cannot be mapped onto the procapsid. This explains part of the hexon distortions found in this region. The implications of translocase-induced DNA twist, end rotation and the coiling of packaged DNA, are discussed. The symmetry mismatches between the head, connector and tail are discussed in relation to the possible [alpha]-helical structures of their DNA channels.

Abstract: The pollen morphology of 15 species (34 specimens) of the genus Lycopus (Lamiaceae, Mentheae) was studied and documented in detail using light microscopy (LM), scanning electron (SEM), and transmission electron microscopy (TEM). The pollen is mostly medium or sometimes small in size, with a circular amb, oblate to prolate in shape, hexacolpate with granular membranes; the exine is bi-reticulate, with unbranched columellae and a continuous, lamellated endexine. The results indicate that Lycopus is stenopalynous; thus the value of pollen characters for taxonomic applications is limited. Some phylogenetic relationships with other related taxa within the tribe Mentheae are also briefly discussed.

889. Moore, J. C., Hansen, D. J., Garnas, R. L., and Goodman, L. R. (Sandranular Carbon Filtration Treatment System for Removing Aqueous Pesticide Residues From a Marine Toxicology Laboratory Effluent. *Govt reports announcements & index (gra&i), issue 11, 1986*.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS, FATE.

ABSTRACT: TD3: Flow-through toxicity tests using marine organisms can generate large volumes of contaminated sea water effluent which should be treated to remove the contaminants before being discharged into the environment. The authors have developed a sand filtration/activated carbon treatment system that removes a diversity of organophosphate, organochlorine and pyrethroid pesticide residues from these effluents. The sand filter removes from 60 to 97% of the chemicals by continuously filtering suspended particulates and associated chemicals as well as by facilitating partitioning of chemicals from water to organic material in the sand filter. Following sand filtration, effluent water slowly percolates through granular activated carbon. Overall, removal efficiencies exceed 90%. The organic material and associated chemicals are backwashed from the sand weekly, separated and concentrated by gravity and packaged for disposal. Chem Codes: Chemical of Concern: PSM Rejection Code: VIRUS.

Summary Bacteriophage [phi]29 is one of the smallest and simplest known dsDNA phages, making it amenable to structural investigations. The three-dimensional structure of a fiberless, isometric variant has been determined to 7.9 A resolution by cryo-electron microscopy (cryo-EM), allowing the identification of [alpha] helices and [beta] sheets. Their arrangement indicates that the folds of the [phi]29 and bacteriophage HK97 capsid proteins are similar except for an additional immunoglobulin-like domain of the [phi]29 protein. An atomic model that incorporates these two domains fits well into the cryo-EM density of the T = 3, fiberless isometric [phi]29 particle, and cryo-EM structures of fibered isometric and fiberless prolate prohead [phi]29 particles at resolutions of 8.7 A and 12.7 A, respectively. Thus, [phi]29 joins the growing number of phages that utilize the HK97 capsid structure, suggesting that this protein fold may be as prevalent in capsids of dsDNA phages as the jelly roll fold is in eukaryotic viruses.

Chem Codes : Chemical of Concern: PSM Rejection Code: BACTERIA.

A method has been developed for three-dimensional image reconstruction of symmetry-mismatched components in tailed phages. Although the method described here addresses the specific case where differing symmetry axes are coincident, the method is more generally

applicable, for instance, to the reconstruction of images of viral particles that deviate from icosahedral symmetry. Particles are initially oriented according to their dominant symmetry, thus reducing the search space for determining the orientation of the less dominant, symmetry-mismatched component. This procedure produced an improved reconstruction of the sixfold-symmetric tail assembly that is attached to the fivefold-symmetric prolate head of [phi]29, demonstrating that this method is capable of detecting and reconstructing an object that included a symmetry mismatch. A reconstruction of [phi]29 prohead particles using the methods described here establishes that the pRNA molecule has fivefold symmetry when attached to the prohead, consistent with its proposed role as a component of the stator in the [phi]29 DNA packaging motor. cryo-EM image reconstruction; [phi]29; pRNA; symmetry mismatch; tail appendages

892. Morel, Jean E., Bachouchi-Salhi, Nacima, and Merah, Zalika (1992). Shape and length of myosin heads. *Journal of Theoretical Biology* 156: 73-90.
Chem Codes: Chemical of Concern: PSM Rejection Code: IN VITRO.

There is controversy concerning the shape and length of myosin heads. In the present paper we try to analyse the data and to draw clear conclusions in this field. When the myosin heads are isolated (S1) from the rest of the molecule, their length is [approximate]12 nm and their shape is close to that of a prolate ellipsoid with an axial ratio [approximate]2[middle dot]3 (in solution) or close to that of a comma when attached to F-actin (with a length of 12-13 nm). When the myosin heads are observed on a whole molecule, their length is [approximate]19 nm and they are pear-shaped. Here we suggest that all these observations are compatible. We believe that, for a whole myosin molecule, a large part of the head-rod joint (S1/S2 joint) is measured with the head, owing to a particularly heavy staining or shadowing of this joint. On the other hand, S1 is probably built up of a head part plus the S1/S2 joint, which is not revealed by the usual techniques (hydrodynamics, X-ray and neutron scattering). Finally, the comma shape would be related to a flexible part in the head region of S1, which is significantly bent when S1 is attached to F-actin, but which would be less bent for S1 in solution. A similar bending also occurs in crystalline S1.

compds., e.g., chloropyrifos, were systematically evaluated for groups contg. analogous structural features. Variations in fragmentation are based on simple org. reactions. While detailed mechanistic interpretations of the laser mass spectra (LMS) were not possible, the qual. features in the LMS obtained from 5 compds. not in the original set could be predicted based on the characteristics of the other OP compds. studied;the success of the prediction lends credence to the qual. models developed for rationalizing the LMS. A specific feature in the LMS of arom. thionophosphates is a thiono-thiolo rearrangement. Detailed investigation into the phenomena involved comparison of LMS obtained from arom. thionophosphates with spectra from electron impact, chem. ionization, field desorption, and secondary ion mass spectrometry. These results showed that the rearrangement in laser mass spectrometry must occur during volatilization while the mol./ion is in the cloud present immediately above the laser impact area. ABSTRACT: Tryptic hydrolysis of benzoyl-DL-arginine p-nitroanilide was competitively inhibited by phenyl and substituted phenyl esters of trans-4-guanidinomethylcyclohexanecarboxylic acid (GMCHA), amidinopiperidine-4-carboxylic acid (APCA), amidinopiperidine-3-carboxylic acid (AP3CA), amidinopiperidine-4-acetic acid (APAA), amidinopiperidine-4-propionic acid (APPA), amidinopiperidine-3-propionic acid (AP3PA), amidinopiperidine-4-butyric acid (APBA), and amidinopiperidine-3-butyric acid (AP3BA). The 4-tert-butylphenyl (tBP) ester of APPA was the most effective inhibitor, its K1 value being 5.0 X 10(-7) M. The free acids and phenols had no inhibitory effect at 10(-3) M. The tBP esters of GMCHA, APPA, and APBA caused 50-60% inhibition of growth of HeLa cells, their effects being dose-dependent, while same esters of APCA, AP3PA, APPA, AP3PA, and AP3BA inhibited the growth by 30-40%. The phenyl esters of these were less inhibitory than the tBP esters. A protease preparation obtained from HeLa cells by sonication and ultrafiltration through a molecular sieve membrane strongly hydrolyzed the fluorescent peptides Boc-Val-Pro-Arg-MCA and Bz-Arg-MCA. This proteolytic activity was not affected by soybean trypsin inhibitor but was strongly inhibited by the tBP esters of GMCHA, APAA, and APBA, their effects roughly paralleling their inhibitions of the growth of HeLa cells.

895. Moriarty, F., Bell, A. A., and Hanson, H. (1986). Does p,p'-DDE thin eggshells? *Environmental Pollution Series A, Ecological and Biological* 40: 257-286.
Chem Codes: Chemical of Concern: PSM Rejection Code: SURVEY.

It is generally accepted that p,p'-DDE causes many species of bird to lay eggs with thinner shells, but the published evidence for this proposition is ambiguous. Data on egg size (measured by maximum length), shape (measured by the ratio of maximum breadth to maximum length), shell thickness (measured indirectly by Ratcliffe's index, I) and p,p'-DDE content (log [mu]g g -1 fresh weight) were therefore examined in samples of eggs taken from three species: two samples from the gannet Sula bassana L., three samples from the shag Phalacrocorax aristotelis L. and six samples from the heron Ardea cinerea L. The value of I is virtually unaffected by changes of egg size but is affected by egg shape, and this variable bias in Ratcliffe's index did in some instances materially affect the conclusions to be drawn from the data. A revised index (J), derived from the prolate spheroid, was therefore developed. The value of J is virtually unaffected by changes of egg size and shape, and yields a much more accurate estimate of the product of the mean shell density and thickness. The conventional negative linear regression of Ratcliffe's index on p,p'-DDE content occurred in many, but not all, of the egg samples that had at least a 10-fold range of p,p'-DDE concentrations. Two other samples both contained two eggs with p,p'-DDE concentrations of not more than 0[middle dot]1 [mu]g g-1 fresh weight. The shell index I increased, or at least did not decrease, until the p,p'-DDE content exceeded about 0[middle dot]1-0[middle dot]2 [mu]g g-1. We suggest that a curvilinear relationship with a maximum turning point is probably a common physiological response to pollutants. http://www.sciencedirect.com/science/article/B75CH-48XD9R3-69/2/d7c7e83a37ad1950b2b8cdfde5af9bea

Fifty pesticides (25 insecticides, 20 fungicides, 3 herbicides, 1 plant-growth regulator, and 1 other compd.) were mutagenic, 5 of which required metabolic activation (S9 mix). Among various chem. groups, org. phosphates, halogenated alkanes, and dithiocarbamates had higher ratios of mutagens. Although 22 of the pesticides tested have been reported to be carcinogenic, 7 of them, i.e., captan [133-06-2], DBCP [96-12-8], EDB [106-93-4], EDC [107-06-2], ETU [96-45-7], HEH [109-84-2], and nitrofen [1836-75-5], were detected as mutagens. Most of the 15 nonmutagenic carcinogens were organochlorine pesticides such as a-BHC [319-84-6], chlorobenzilate [510-15-6], DDT [50-29-3], dieldrin [60-57-1] and quintozene [82-68-8]. CAS Registry Numbers: 52-68-6; 60-51-5; 63-25-2; 122-14-5; 300-76-5; 315-18-4; 732-11-6; 1933-50-2; 2921-88-2; 3383-96-8; 6164-98-3; 13171-21-6; 14816-18-3; 16752-77-5; 22248-79-9; 30560-19-1; 35367-38-5 Role: BIOL (Biological study) (compatibility of, with Bacillus thuringiensis kurstaki) The compatibility of B. thuringiensis with 27 chem. insecticides representing organophosphorus and carbamate insecticides, pyrethrins, chlordimeforms, urea derivs., and an antifeedant were studied by way of their effects on germination of the bacterial spores, replication of vegetative cells and spore staining, and refractive index characteristics. Carbamates were generally more compatible with B. thuringiensis than were the other insecticide groups tested. Tech. formulations were less harmful to the bacteria than wettable powders which were less harmful than emulsifiable concs. Of the 27 pesticides, those most compatible with B. thuringiensis were Orthene [30560-19-1], Dylox [52-68-6], Lannate [16752-77-5], Sevin (I) [63-25-2], Zectran [315-18-4], and Dimilin [35367-38-5]. These insecticides are considered recommendable for use in integrated control operations with B. thuringiensis if the target insects are susceptible to them and provided that due to regard is given to the environmental implications of their use. ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. A case history of petroleum contamination migration with the groundwater is presented. Air, soil-gas, and groundwater monitoring were used to investigate the source and extent of petroleum contamination in an elementary school located adjacent to a gasoline station and a petroleum tank farm. The school had been closed when students and teachers reported noxious odors. Groundwater and soil-gas data indicated that a plume of contamination following the local groundwater gradient had appeared between a petroleum tank known to have leaked 20,000 gal of gasoline and the school building. Air samples revealed contamination beneath the school and within the school itself. Caution is warranted when soil-gas surveys are used to determine the location of a groundwater contaminant plume. Groundwater recharge from precipitation can markedly influence the migration rate of a contaminant plume and can increase the ability of vaporous components to percolate upward. The elementary scho

Abstract: The management of contaminated soils and wastes is a matter of considerable human concern. The present study evaluates the genotoxic potential of aqueous extracts of two soils (leachates) and of bottom ash resulting from municipal solid waste incineration (MSWIBA percolate), using amphibian larvae (Xenopus laevis). Soil A was contaminated by residues of solvents and metals and Soil B by polycyclic aromatic hydrocarbons and metals. MSWIBA was predominantly contaminated by metals. Two genotoxic endpoints were analysed in circulating erythrocytes taken from larvae: clastogenic and/or aneugenic effects (micronucleus induction) after 12 days of exposure and DNA-strand-breaking potency (comet assay) after 1 and 12 days of exposure. In addition, in vitro bacterial assays (Mutatox[registered] and Ames tests) were carried out and the results were compared with those of the amphibian test. Physicochemical analyses were also taken into account. Results obtained with the amphibians established the genotoxicity of the aqueous extracts and the comet assay revealed that they were genotoxic from the first day of exposure. The latter test could thus be considered as a genotoxicity-screening tool. Although genotoxicity persisted after 12 days' exposure, DNA damage decreased overall between days 1 and 12 in the MSWIBA percolate, in contrast to the soil leachates. Bacterial tests detected genotoxicity only for the leachate of soil A (Mutatox). The results confirm the ecotoxicological relevance of the amphibian model and underscore the importance of bioassays, as a complement to physico-chemical data, for risk evaluation.

A database of lowest-obsd.-adverse-effect level (LOAEL) was assembled by extg. toxicity information from 104 U.S. EPA documents, 124 National Cancer Institute/National Toxicol. Program (NCI/NTP) reports, and 6 current reports from the literature. A regression model, based on 234 chems. of diverse structures and chem. classes including both alicyclic and arom. compds., was developed to assess the chronic oral LOAELs in rats. The model was incorporated into an automated computer package. Initial testing of this model indicates it has application to a wide range of chems. For about 55% of the compds. in the data set, the estd. LOAELs are within a factor of 2 of the obsd. LOAELs. For over 93%, they are within a factor of 5. Because of the paucity or absence of long-term toxicity data, the public health and risk assessment community could utilize such QSAR models to det. initial ests. of toxicity for the ever-increasing nos. of chems. that lack complete pertinent data. However, this and other such models should be used only by expert toxicologists who must objectively look at the ests. thus generated in light of the overall wt. of evidence of the available toxicol. information of the subject chem.(s). Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

Banana and other horticultural produce cultivation, together with the population increase, has led to coastal aquifer degradation in the Canary Islands. A detailed field study to track nitrogen degradation and transport through a banana plantation soil into the aquifer is presented. The main objective of the study is to understand and quantify the hydrological behavior of the system, and quantify nitrogen leaching. The hydrogeological study of the area shows that the thin terraced soil is set on top of several layers of fractured basalt down to a massive formation where the polluted aquifer is found. When water leaves the soil profile, it is likely to quickly percolate along the preferential paths (cracks) through the basaltic layers and it is intercepted by lateral interflow in a mixing ratio of 25% irrigation drainage plus 75% interflow, before it reaches the aquifer. The soil water balance shows that most of the drainage (18% of the total irrigation+rainfall) is produced during the crop highest water demand period and during the short rainy season when no irrigation is applied. Monitoring of the soil solution showed that very high nitrate concentrations (50-120 mg/l N---NO3) are present throughout the experimental period. The high water fluxes and nitrate concentration at the bottom of the soil profile produce a yearly loss of 48-52% of the total N applied (202-218 kg N/ha per year). Monitoring of water from springs below the experimental area shows that the nitrate lixiviates are diluted around 60% before reaching the aquifer, after mixing with the lateral flow. Smaller and more frequent applications of both N and water would help to reduce the environmental impact of the system. 907. Murthy, N. S. and Knox, J. R. (1976). Small-angle X-ray scattering studies of Escherichia coli-asparaginase. *Journal of Molecular Biology* 105: 567-575.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

Small angle X-ray scattering studies on Escherichia coli-asparaginase solutions show that the enzyme has a radius of gyration of 34.0 A +/- 0.5 A at pH 7. The radius of gyration of the dissociated monomer is 16.0 A +/- 1.0 A; it has the general shape of a prolate ellipsoid with an axial ratio of 1.4. A tetramer of four such ellipsoids arranged with 222 symmetry gives good agreement between measured and calculated radii of gyration if the distance between subunit centers is 43 A. The tetramer dissociates on dilution below 1% and at pH values below 3.0. Acid-induced denaturation at pH 2.0 is irreversible in contrast to the reversible guanidine-HCl-induced denaturation. http://www.sciencedirect.com/science/article/B6WK7-4DN8VPN-BT/2/3fcc5b39f4df50f80ace66defa5ae77f

ABSTRACT: This study investigated the effectiveness of vegetated buffer strips for removing contaminants in runoff from grassed plots (slope 15%) after application of cattle slurry. Plots (8 x 8 m2 or 8 x 3 m2) received slurry or inorganic fertilizer, and then simulated rainfall (1, 7 and 21 days after slurry/fertilizer application); after each event, runoff and percolates were sampled at various distances downslope (2, 4, 6, and 8 m), and analysed for Cl-, Na+, K+ and faecal bacteria contents. Contaminant concentrations were markedly higher in runoff from the slurry-amended plots than in runoff from the fertiliser-amended plots. After the first rainfall event, some contaminant concentrations in runoff from the slurry-amended plots declined with distance downslope (i.e. with buffer strip width), supporting the relative efficacy of the strip for retaining pollutants. After the second and third rainfall events, by contrast, our results suggest remobilisation of contaminants retained during the first event. Faecal bacteria levels (especially streptococcus levels) remained high throughout the study, even in percolates and runoff collected 8 m downslope after the third rainfall event, and indeed even downslope of the adjacent fertilizer-amended plots (indicating lateral movement): this suggests that bacterial contamination may be the most significant risk arising from slurry application.

912. Nagayama, T., Kobayashi, M., Shioda, H., Ito, M., and Tamura, Y. (1995). Relationship Between Pesticide Residues in Fruit Peel and Flesh. *Journal of the food hygienic society of japan* 36: 383-392.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Pesticide residues in or on fruits and translocation of pesticide from the peel to the flesh were investigated. Except for water-soluble pesticides, the highest ratio of the concentration in the flesh to that in the peel was found with imidazole and phenoxy pesticides, followed by carbamate pesticides. Organochlorine and organophosphorus pesticides gave low ratios. The regression equation log (Cf)= -1.22+0.924 log (Cp) (gamma=0.892), where Cf is the pesticide concentration in flesh (ppm) and Cp is that in peel (ppm), was obtained for the relation between imazalil residues in lemon peel and flesh. The relation between the concentration ratio of the flesh to the peel and the pesticide solubility in water was given by: Cr = -0.99 + 2.41oncentration ratio (%) in the flesh and the peel and Sw is the pesticide solubility in water (mg).

915. Naim, Mona M. and Abd El Kawi, Mervat A. (2003). Non-conventional solar stills Part 1. Non-conventional solar stills with charcoal particles as absorber medium. *Desalination* 153: 55-64.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

A solar still in which charcoal functions both as heat absorber medium and as wick has been constructed. The still presents a 15% improvement in productivity over wick-type stills, is cheap, simple to construct, and in addition has the advantages of low thermal capacity, lightweight and ease of operation. It is made of plastic outer rectangular body in which salt water is allowed to percolate through a charcoal bed of particles that extends the length of the still, and above which a glass plate is made to cover the still at an optimum distance from the charcoal bed. The still bottom is insulated by a suitable layer of sawdust and the still is mounted on a wooden frame of adjustable inclination. Factors such as size range of charcoal particles, brine flowrate, and still inclination to the horizontal have been investigated. It was found that at high flowrates both the coarse particles followed by the intermediate size gave the best productivities, whereas at moderate flowrates the finest charcoal gave the best result. At low flowrates, the three sizes gave practically comparable productivities. (Pow) of agricultural chems. was investigated, and the Pow values of 46 agricultural chems. were detd. by the proposed method. Then the sorption behavior of these chems. in solid-phase extn.(SPE) was investigated using eight different types of Sep Pak Plus cartridges and five eluents in the relation to these Pow values. The chems. with a log Pow below about 4.5 were completely retained onto the alkyl-modified silica and polystyrene cartridges, and easily eluted with any of the eluents except for n-hexane. The recovery of the chems. with higher Pow values decreased with the increase of Pow values due to incomplete elution, but the extent of elution could be improved by adding methanol to the sample soln. Moreover, by back flush elution the chems. with a log Pow below about 5.5 could be completely recovered without the addn. of methanol. However, in order for the complete elution of the extremely hydrophobic chems. the addn. of methanol was required even with the back flush. The results suggest that the Pow values evaluated with the HPLC method can be used as the most

useful key parameter for the selection of the key conditions in SPE. It is interesting that the cyanopropylated-silica cartridge can retain the more hydrophobic chems. so that it could be used for selective reversed-phase SPE for the extremely hydrophobic chems. Recovery was related closely to their n-octanol/water partition coeffs. Those compds. with high coeffs. were easily sorbed, but were difficult to elute. The extent of elution could be improved by adding CH_3OH to the sample soln. Results suggested the most important solid-phase extn. conditions for enrichment and sepn. can be selected approx. using the partition coeff. as a key parameter. The effect humic acid and surfactants on recovery was also studied. Suggested guidelines for efficient enrichment and sepn. by solid-phase extn. are presented. Some applications were tested and good results were obtained. [on SciFinder (R)] 0003-2654 arom/ compd/ detn/ water;/ agricultural/ chem/ detn/ water;/ solid/ phase/ extn/ org/ compd/ water

A multiresidue method capable of detecting over 200 analytes was used. In 5784 domestic samples a total of 676 residue findings were made. Of these, 32 (0.55%) were in violation of Canadian Max. residue limits (MRLs). In 16,198 imported products, 464 of 3193 residue findings exceeded MRLs, corresponding to a violation rate of 2.86%. One-half of domestic violations resulted from commodity-pesticide combinations for which these are no Canadian approvals. [on SciFinder (R)] 1060-3271 pesticide/ residue/ food/ commodity/ Canada

Abstract: Porous plates or cups are commonly used to collect soil solution samples in field studies or from intact soil columns. Some commonly used materials for porous plates may adsorb soil solution constituents such as phosphorus (P). An alternative to using a porous plate is to use a membrane filter with a known pore size and bubble point. The objective of this study was to evaluate the utility of polyethersulfone membranes (pore size 0.45 (mu)m and bubble point >200 kPa) to extract soil solution from in situ soils and intact soil columns for phosphate analysis. In situ soil solution samplers were constructed from modified reusable polysulfone membrane filter holders equipped with polyethersulfone membranes (47 mm diameter). A -10 kPa vacuum was maintained in the samplers, which enabled soil solution collection at soil water potentials of 0 to -4 kPa in loamy sand, 0 to -10 kPa in sandy loam, and 0 to -12 kPa in sandy clay loam soils. In a laboratory study, soil solution samplers continued to hold a vacuum to -77 kPa soil water potential. Soil solution samplers were further evaluated in a field study at 45-, 90-, and 135-cm depths in two soils. Samplers operated with relatively few difficulties for the first 12 months of field evaluation. Membranes apparently dried during periods of low soil water potential but increases in soil moisture were sufficient to rewet the membrane. Sampler failures in the field increased during 13-18 months because aged vacuum tubing and root interferences with samplers at 45 cm. Improvements in sampler design may improve the durability for implementation in long-term field experiments. Membrane filters worked near flawlessly to maintain unsaturated conditions in intact soil columns. The filter units facilitated easy collection of soil water from the intact soil columns without altering the chemical composition of the percolate. Copyright (copyright) Taylor & Francis Group, LLC.

Abstract: Excess phosphorus applied to soils with low P adsorption capacities can enter surface water via leaching and subsurface transport, thereby negatively impacting water quality. Computer

simulation models can be used to describe the effects of management practices on P leaching losses, provided the models are appropriately validated. The objectives of this research were to modify and validate P subroutines in the GLEAMS (Groundwater Loading Effects of Agricultural Management Systems) model to more accurately reflect P sorption and desorption, and then use the modified model to determine crop and waste management effects on long-term P leaching losses below the root zone of a grazed pasture with >20-year history of swine lagoon liquid application and considerable P buildup in the soil profile. GLEAMS was modified with the Langmuir equation to partition labile P between adsorbed and solution phases. The modification improved predictions of percolate P concentrations and soil P accumulation in acid sandy soils receiving waste-based P additions. The modification also increased model sensitivity to changes in crop and P management. The modified model predicted that P-based swine lagoon liquid applications would decrease P leaching by >20 kg ha⁻¹ year ⁻¹ compared to N-based applications. Eliminating all P applications decreased the predicted P leaching losses by less than 1 kg ha⁻¹ year⁻¹ compared to P-based swine lagoon liquid application. Results show that P can continue leaching from P-saturated soils even in the absence of P additions. (copyright) 2006 American Society of Agricultural and Biological Engineers.

ABSTRACT: The stability of 89 pesticides (17 organochlorine, 33 organophosphorus, 8 pyrethroid, 12 carbamate, and 19 other pesticides) in 6 kinds of organic solvents (methanol, ethanol, 2-propanol, ethyl acetate, n-hexane, and acetone) was investigated using gas chromatography/mass spectrometry (GC/MS). All of the investigated pesticides were stable in all of the tested organic solvents during storage for 6 hours at room temperature in the dark except captafol, captan, phosmet, chinomethionat, and dicofol. However, the decreases of captafol, captan, phosmet, and chinomethionat were observed in methanol. The decreases of captafol, captan, and phosmet were also observed in ethanol. Moreover, the decrease of dicofol was observed in acetone. The decrease of captafol dissolved in methanol at a concentration of 2 micrograms/ml was faster than those of captan, phosmet, and chinomethionat; the residual captafol was 75% after 30 min of storage. Dicofol dissolved in acetone also decreased during storage in a refrigerator. 4,4'-dichlorobenzophenone (DCBP) and chlorobutanol were detected in the acetone solution of dicofol after storage. Furthermore, it was found that dicofol was decomposed by acetone at an injection port, and DCBP and chlorobutanol were formed when it was injected into GC with acetone.

Supercrit. fluid extn. (SFE) conditions for multiresidue anal. of pesticides are evaluated using diatomaceous earth (Celite) spiked with 88 pesticides (16 organochlorine, 33 organophosphorus, 8 pyrethroid, 12 carbamate, and 19 other pesticides). The SFE parameters considered are CO2 d., CO2 flow rate, extn. temp., static and dynamic extn. times, trap temp., and addn. of modifier. SFE without modifier is insufficient to ext. polar pesticides from fortified Celite. The addn. of water to Celite is most effective in enhancing the recoveries of pesticides. Methanol is also an effective modifier, but the recovery of captafol, captan, phosmet, and chinomethionat decreases as time

goes on after the addn. of methanol. The best obtained conditions of SFE (2.0 g sample) are as follows: 0.40 mL water as a modifier, 0.70 g/mL CO2 d., 50 Deg extn. temp., 2.0 mL/min CO2 flow rate, 3.0 min static extn. and 20.0 min dynamic extn. The extd. pesticides are collected on an octadecylsilane trap at 30 Deg. Quant. anal. of the 88 pesticides is performed by gas chromatog.-mass spectrometry using the selected ion monitoring mode. Recoveries from fortified Celite are >90% for 79 pesticides and >70% for the other pesticides, except acephate, methamidophos, and propamocarb. The relative std. deviations of the recoveries are <5% for almost all of the pesticides. [on SciFinder (R)] 0021-9665 supercrit/ fluid/ extn/ pesticide

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. The National Animal Health Monitoring System (NAHMS) (Round 2) for Tennessee collected baseline data on the preventive (as opposed to therapeutic) use of drugs from 60 beef cow-calf herds selected by a random, stratified, two-stage sampling plan. Counties were selected randomly with replacement for three herd-size strata, and herds were selected within counties by an area-frame method. Data were collected during monthly interviews for 1 year (1987-1988). Tennessee beef cattle were medicated with 31 drugs to prevent diseases. The drugs most frequently used were anthelmintics and insecticides. The diseases against which preventive drugs were most frequently used were external parasites, intestinal parasites, 'pink eye' (keratoconjunctivitis), anaplasmosis, and respiratory infections. Ivermectin was the most frequently used anthelmintic and the most frequently used drug. Levamisole, fenbendazole, and thiabendazole were also frequently used anthelmintics. The most frequentl

Chem Codes: Chemical of Concern: PSM Rejection Code: SURVEY, BACTERIA.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Source separated biowaste was stored in containers at temperatures ranging from 16ęC to 29ęC in a climate chamber for two weeks, simulating outdoor storage in a domestic waste collection system. Samples of exuded percolate were collected after 3, 4, 6, 8, 10, 12 and 14 days and analyzed for content of microorganisms and endotoxin. Throughout the storage period, the mean concentrations (GM) of total microorganisms ranged from 5.0 to 12 of endotoxin were between 0.54 and 1.530 mug ml-1). The maximum levels of microorganisms and endotoxin in the percolate were stable during storage and no significant difference was found between storage times of one or two weeks, which corresponds to common Danish collection frequencies of biowaste. Analyses of the microflora indicated dominance of bacteria as demonstrated by almost equal concentrations obtained by aerobic and anaerobic cultivation (2.8 to 9.0to 12t of the microflora (below 0.5% of the total number of microorganisms) and m

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. The potential leaching and availability of nitrogen in biosolids and biosolid-amended glaciated soil were investigated using mineralization and column studies. Aerobic and anaerobic mineralization studies were conducted to assess nitrogen mineralization potential from biosolid-amended glaciated soils and estimate long- and short-term mineralization rates of products. Semicontinuous column studies were conducted to assess the leachability of nitrogen from biosolid-amended soil under simulated uns uct had the greatest mineralization potential (based on unmixed biosolids) at 5 317 mg N/kg, followed by compost (324 mg N/kg) and CKD biosolids (58 mg N/kg). Nitrogen mineralized for the anaerobic test (mixed with soil) varied from 56 to 90% of the total nitrogen and for the aerobic test varied from 19 to 57%. The CKD biosolids percolate consisted primarily of nitrate and nitrite, whereas the predominant nitrogen species found in compost and pellet biosolids percolate was ammoni

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: PESTAB. The accurate measurement of respired amounts of inhaled pesticides was improved by connecting a twin cartridge face-mask to a gas-meter. The apparatus was utilized to determine amounts of inhaled pesticides in 2 field trials; one in an apple orchard where diazinon was being used, and another in a rice paddy where phosmet was being used. The results were compared to data obtained by an impinger collection apparatus. The pesticide was collected on micron-filter pads placed in the face-masks. The collected pesticide was removed from the filter pad by chloroform washing and measured by gas chromatography. The amount of pesticide collected divided by the respiration rate was calculated to be the concentration of respired pesticide. The amount of pesticide collected divided by the time period of application was calculated to be the amount of inhaled pesticide/unit time. Results were generally higher when determined by the filter pad method than when determined by the impinger method. Respired phosmet was 0.914 mg/m3 as determined by the filter pad collection data and 0.952 mg/m3 by impinger collection data. Respired diazinon was calculated to be 0.090 mg/m3 from filter pad data and 0.053 mg/m3 from inpinger collection data.

Chem Codes: Chemical of Concern: PSM Rejection Code: METHODS.

ABSTRACT: PESTAB. A method for determining the concentration of pesticide dust in inhaled air was studied using 3% phosmet dust and fenitrothion emulsive concentrate diluted 500-fold. At first, the air containing the dust was suctioned through a holder provided with a filter pad and a millipore glass filter; collecting efficiency was measured by the amount of dust collected on the filter pad and the amount of dust to pass through the millipore filter. Results obtained by the conventional impinger method were compared with results obtained by pad method. Using a commercial dust-prevention mask provided with a filter pad, the concentration of the aerial dust was determined. A high dust-collection efficiency was obtained: 30 l/min dust on the filter pad and 5.5 mg dust on the millipore glass filter, corresponding to aerial concentrations of 2.083

mg/m3 and 0.005 mg/m3, respectively (collecting efficiency 99.8%). Results were similar to those obtained by the conventional method of using impinger. In determining aerial mist of diluted emulsion concentrate, results were similar.

ISSN: 0022-2062
Descriptors: Correlation between pollen size and ploidy level
Descriptors: Deutzia
Descriptors: Pollen morphology
Descriptors: Taxonomy
Abstract: The morphology, exine structure, size and fertility of the pollen grains of 8 species, 5 varieties and 1 form of the genus Deutzia from Japan were examined with light and scanning electron microscopy. The results indicated that the pollen grains are 3-colporate, prolate spheroidal or subprolate, semitectate, reticulate or microreticulate with tectum, and the shape, tectum-pattern and structure of pore of the pollen grains are similar in all examined taxa. The pollen grains have a high stainability over 90 %. A correlation between the pollen size and the ploidy level was found. The value of pollen characters for taxonomic purposes and position of taxa studied on Deutzia were discussed.

934. Noda, Haruhiko (1955). Physico-chemical studies on the soluble collagen of rat-tail tendon. *Biochimica et Biophysica Acta* 17: 92-98.
Chem Codes: Chemical of Concern: PSM Rejection Code: IN VITRO.

From an extraction solution of rat-tail tendon with dilute acetic acid, a major protein component which was assumed to be responsible for reprecipitating striated fibers was purified. By measuring sedimentation constant, viscosity and diffusion constant, its molecular weight and shape were calculated. The molecular weight was found to be about 700, 000. Assuming the molecules to be prolate ellipsoids of revolution, the long axis was calculated to be 5, 000 A and the short axis 18 A. http://www.sciencedirect.com/science/article/B73G9-47KGRYM-75/2/160837dfea163382b08f409e36323f8d

937. Nonomura, Yoshiaki, Blobel, Gunter, and Sabatini, David (1971). Structure of liver ribosomes studied by negative staining. *Journal of Molecular Biology* 60: 303-308.
Chem Codes: Chemical of Concern: PSM Rejection Code: IN VITRO.

Unfixed ribosomal subunits obtained by puromycin treatment at high ionic strength from free polysomes of rat liver and their dimers, ribosome monomers and free polysomes, were examined electron microscopically after negative staining with uranyl acetate. Small subunits are elongated and slightly bent prolate-shaped bodies which are viewed as straight (~ 230 A x 140 A) or curved profiles (230 A x 120 A). These images show a transverse dense line or partition, which divides them into two regions of unequal size (length ratio 1:2). Small subunits dimerize in an antiparallel fashion, joining to each other through their concave sides at the smaller regions in their surface. Large subunit profiles are of three main types, (i) Rounded profiles, ~ 230 A in diameter, which correspond to views on a flattened face to which other large subunits or small subunits can bind, (ii) Asymmetric profiles which have the shape of a skiff. These are approximately triangular, with one flattened or concave side (~ 230 A long), which shows a notch (~ 40 A) towards the blunted side of the skiff, and two convex sides of unequal length, (iii) Triangular profiles more nearly equilateral than the previous ones. Of the two enantiomorphic types of large subunit profiles of type (ii), one is almost exclusively observed. Large subunit profiles types (ii) and (iii) are seen in "frontal" and "lateral" views, respectively, of the monomeric ribosome. Large subunit dimer profiles are formed by pairs of profiles (ii) or (iii). In the first case the separation between subunit profiles is oblique to the long axis of the dimer image. Two main views of the monomeric ribosome were observed. Frontal views have the small subunit visible throughout their length. The notch on the flattened side of large subunit profile type (ii) is seen as a dense spot immediately below the small subunit partition. If frontal views are oriented with the small subunit horizontally and towards the top, in most cases the small subunit partitions and the large subunit notches are to the left of the observer. In lateral views small subunits are seen as small rectangular profiles (140 A x 120 A) bound towards one end of the flattened side of large subunit profiles type (iii). If lateral views are oriented with the small subunit towards the top, most frequently the small subunit is to the right of the observer. Frontal and lateral views of the monomeric ribosome are interconvertible by tilting. A model was constructed which explains the images and the changes introduced by tilting. Within polysomes, lateral views of the monomeric ribosome were more frequent than in monomer samples. The strand joining ribosomes within a Polysome can be followed up to the dense spot under the small subunit partition or up to the junction between subunits. http://www.sciencedirect.com/science/article/B6WK7-4DPBW63-2P/2/dd9d6ce84e77e2c17e9a99e17bdf2d91

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE, MODELING.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Intensive pine forest management practiced in the southern United States relies heavily on seed orchards to produce genetically improved seedlings to achieve high productivity. One of the most critical problems is the control of seed and cone insects requiring heavy and frequent applications of insecticides. Hydrologic modeling of insecticide fate in surface water and ground water is a useful technique for evaluating the environmental fate of the applied insecticides. The GLEAMS (groundwater loading effects of agricultural management systems) model was used to evaluate the differences between fate of insecticides at four pine seed orchard sites in different physiographic regions of the southern United States. A 50-year simulation period was used. Insecticides selected for simulation were carbofuran, azinphosmethyl, fenvalerate, and permethrin. The simulations of insecticide losses in storm flow and percolate at each of the seed orchards demonstrated the importance of th

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. During the period of 1985 to 1988, municipal water supply sources in Atlantic Canada were sampled and analyzed for various compounds including major ions, nutrients, heavy metals, pesticides and synthetic organic chemicals. Both surface and ground water sources were sampled. Ninety-eight percent of supply sources were within the health-related maximum acceptable concentrations of the Guidelines for Canadian

Drinking Water Quality (Health and Welfare Canada 1987), and eight-five percent within the aesthetic guidelines. A geographic information system was used to classify the municipal sources by surrounding land-use and comparisons made to nitrate-N. All samples reported as 1.0 mg.L-1 or greater were from ground water supplies in areas classed as high agricultural use. Though a direct input from agriculture was established for two wells, the source of nitrate-N at the remaining sites was attributed to soil-N and/or fertilizer-N.

Citations: 9) Obana, H; Anal Commun 1997, 34, 253 A high-throughput multiresidue anal. of pesticides in non-fatty vegetables and fruits was developed. The method consisted of a single extn. and a single clean-up procedure. Food samples were extd. with Et acetate and the mixt. of ext. and food dregs were poured directly into the clean-up column. The clean-up column consisted of two layers of water-absorbent polymer (Aquapearl A3; upper) and graphitized carbon (lower), which were packed in a reservoir (75 mL) of a cartridge column. The polymer removed water in the ext. while the carbon performed clean-up. In a recovery test, 110 pesticides were spiked and av. recoveries were more than 95% from spinach and orange. Most pesticides were

recovered in the range 70-115% with RSD usually <10% for five expts. The residue analyses were performed by the extn. of 12 pesticides from 13 samples. The two methods resulted in similar residue levels except chlorothalonil in celery, for which the result was lower with the proposed method. The results confirmed that the proposed method could be applied to monitoring of pesticide residue in foods. The method involves the use of a high capacity absorbent polymer for water as a drying agent in extn. from wet food samples and of a graphitized carbon column for clean-up. A homogeneously chopped food sample (20 g) and polymer (3 g) were mixed to absorb water from the sample and then 10 min later the mixt. was vigorously extd. with Et acetate (100 mL). The ext. (50 mL), sepd. by filtration, was loaded on a graphitized carbon column without concn. Addnl. Et acetate (50 mL) was also eluted and both eluates were concd. to 5 mL for anal. The procedure for sample prepn. was completed within 2 h. In a recovery test, 107 pesticides were spiked and av. recoveries were more than 80% from asparagus, orange, potato and strawberry. Most pesticides were recovered in the range 70-120%, with usually less than a 10% RSD for six expts. The results indicated that a single extn. with Et acetate in the presence of polymer can be applied to the monitoring of pesticide residues in foods. 942. Oblath, S. B. (Radionuclide Release From Low-Level Waste in Field Lysimeters. *Govt reports announcements & index (gra&i), issue 06, 1987.*
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: TD3: A field program has been in operation for 8 years at the Savannah River Plant (SRP) to determine the leaching/migration behavior of low-level radioactive waste using lysimeters. The lysimeters are soil-filled caissons containing well characterized wastes, with each lysimeter serving as a model of a shallow land burial trench. Sampling and analysis of percolate water and vegetation from the lysimeters provide a determination of the release rates of the radionuclides from the waste/soil system. Vegetative uptake appears to be a major pathway for migration. Fractional release rates from the waste/soil system are less than 0.01% per year. Waste-to-soil leach rates up to 10% per year have been determined by coring several of the lysimeters. The leaching of solidified wasteforms under unsaturated field conditions has agreed well with static, immersion leaching of the same type waste in the laboratory. However, releases from the waste/soil system in the lysimeter may be greater than predicted based on

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: TD3: The special wasteform lysimeters at the Savannah River Laboratory are designed to measure the migration of radionuclides from commercial power reactor wasteforms under unsaturated conditions in a humid site. Operation of the lysimeters under field conditions allows prediction of the behavior of solid low-level wasteforms (concrete and polymer) in actual burial trenches. Analysis of the percolate water from the lysimeters has been performed regularly since emplacement of the waste in March 1982. Co-60 and Sr-90 have migrated through the soil to the sumps. Cs-137 has been detected only in water collected from the soil column and has not yet migrated to the sumps. The results of this unsaturated leaching can be compared to the performance of identical wasteforms in saturated leach tests. 3 references, 1 figure, 3 tables. ABSTRACT: Here we show that the extent of electron flow through the cbb(3) oxidase of Rhodobacter sphaeroides is inversely related to the expression levels of those photosynthesis genes that are under control of the PrrBA two-component activation system: the greater the electron flow, the stronger the inhibitory signal generated by the cbb(3) oxidase to repress photosynthesis gene expression. Using site-directed mutagenesis, we show that intramolecular electron transfer within the cbb(3) oxidase is involved in signal generation and transduction and this signal does not directly involve the intervention of molecular oxygen. In addition to the cbb(3) oxidase, the redox state of the quinone pool controls the transcription rate of the puc operon via the AppA-PpsR antirepressor-repressor system. Together, these interacting regulatory circuits are depicted in a model that permits us to understand the regulation by oxygen and light of photosynthesis gene expression in R.SPHAEROIDES:

(Analyte), ANST (Analytical study) (detn. of, as ozonization products of organophosphorous pesticides, in water); 10028-15-6 (Ozone) Role: MSC (Miscellaneous) (organophosphorous pesticide degrdn. by, in water, as pollutants, oxons from); 7732-18-5 (Water) Role: MSC (Miscellaneous) (ozonization in, of organophosphorous pesticides, as pollutants, oxons from) Primary ozonization degrdn. products of organophosphorous pesticides in water were studied by gas chromatog.-mass spectrometry. and the oxidn. pathways of diazinon, fenthion (MPP), and edifenphos (EDDP) were proposed. Mass-spectra of ozonization products of the evaluated 17 organophosphorous pesticides suggested that they were oxons. Organophosphorous pesticides were converted to oxons in accordance with prodn. of SO42- as their thiophosphorile bonds were oxidized by O3 into phosphorile bonds. Although oxons were stable against ozonization, they were further hydrolyzed into trialkyl phosphate and other hydrolysis products. However, in MPP, thiomethyl radicals were oxidized prior to thiophosphorile bonds and MPP-sulfoxide was produced. MPP-sulfone, MPP-sulfoxide-oxon and MPP-sulfone-oxon were also generated from MPP. Two major oxidn. products were obtained from bis-dithio type ethion. EDDP of the phosphate type was resistant to ozonization, but its oxidn. products were detected after hydrolysis. Citations: Yamada, M; J Bacteriol 1995, 177, 1511 Each of the Escherichia coli tester strains in the WP3101P-WP3106P series contains an F' plasmid with a different base substitution mutation within the lacZ gene. Each of the six possible base substitution mutations, therefore, can be assayed with these strains by Lac+ reversion. The authors used the strains to characterize the mutational profiles of 21 chem. mutagens, including alkylating agents, base analogs and oxidative compds. The authors also assayed the mutagens with Salmonella typhimurium tester strains TA7002, TA7004 and TA7005, which detect A.T->T.A, G.C->A.T and G.C->T.A mutations, resp., and the authors compared the sensitivity and specificity of the two systems. Escherichia coli strain WP3102P was more sensitive than the S.typhimurium strains to G.C->A.T transitions induced by N4-aminocytidine, 5-azacytidine, cumene hydroperoxide (CHP), t-Bu hydroperoxide (BHP), N-ethyl-N'-nitro-N-nitrosoguanidine (ENNG), Me methane sulfonate and N-ethyl-N-nitrosourea (ENU), while the reverse was true for G.C->A.T transitions induced by 2-aminopurine and phosmet. Escherichia coli strain WP3104P, which detects G.C->T.A transversions, was superior to the S.typhimurium strains in detecting transversions induced by N4-aminocytidine, 5-azacytidine, 5-diazouracil, CHP, BHP, ENNG, ENU, 4-nitroquinoline 1-oxide (4-NQO) and 3-chloro-4-(dichloromethyl)-5-hydroxy-2(5H)-furanone (MX). Escherichia coli WP3105P was also more sensitive than S.typhimurium to A.T->T.A transversions induced by N-methyl-N-nitrosourea (MNU), CHP and 4-NQO, but it was less sensitive to those induced by ENNG, ENU and 2-aminopurine. The present results indicate that the E.coli Lac+ reversion system with tester strains WP3101P-WP3106P is as sensitive as the S.typhimurium His+ reversion system for the detection of specific mutations induced by a variety of direct mutagens. Abstract: The forest model series ForM-S currently includes four modules addressing (1) water fluxes (ForHyM), (2) soil temperature (ForSTeM), (3) ion fluxes (ForIoM), and (4) primary production and nutrient cycling in upland forest stands (ForSVA). The modules require climate records (air temperature, precipitation volume), total atmospheric ion deposition and descriptive site information as input. The models are designed to capture the dynamics of the simulated processes at monthly (ForHyM, ForSTeM, ForIoM) and annual scales (ForSVA). ForHyM and ForSTeM have been verified across diverse sites in North America. For the Solling dataset, ForHyM closely reproduced hydrologic data (monthly throughfall, forest-floor percolate, soil percolate) without further calibration. With ForSTeM and ForHyM, snowpack water, soil temperatures, and frost penetration were simulated. ForIoM simulations compared favourably with the concentration and flux data for individual ion species (H super(+), K super(+), Na super(+), NH super(+) sub(4), Cl super(-), NO super(-) sub(3), Ca super(2+), Mg super(2+), SO sub(4) super(2-), Al super(x+)) in throughfall, forest-floor percolate and soil percolate after calibrating one or two parameters for the forest canopy, the forest floor, the mineral soil. Nutrient losses, nutrient uptake rates, base cation replenishment rates within the soil, and biomass production and accumulation for the main stand compartments (foliage, wood, fine roots, forest floor) were simulated with ForSVA. The resulting calculations about cumulative soil leaching losses for Ca, Mg, K, NH sub(4)-N, NO sub(3)-N, and SO sub(4)-S were in good agreement with observations.

Patent Application Country: Application: EP
Priority Application Country: JP
Priority Application Number: 89-251858
Priority Application Date: 19890929 A method of evaluating the physiol. and structural characteristics of medicinal substances uses crystal oscillators having lipid films to det. correlations of (A) physiol. activity factors and/or structural characteristics of the medicinals with (B) change in frequency, adsorption amts., lipid film-water partition coeffs., or other lipid film interaction characteristic. The antimicrobial activity of long-chain fatty acids against Gram-pos. bacteria showed good correlation with the partition coeff. using a lipid film of polystyrene sulfonic acid dialkylammonium salt. The partition coeff. of 70 substances in this film correlated well with Draize scores as an indication of toxicity. [on SciFinder (R)] G01N029-00. The pesticides could be detd. within the range 0.02-0.75 ng/mL in water with relative std. deviations (R.S.D.s) of 1.0-31.4% (except for MPP, 1.0-10.9%). The detection limits of the pesticides were 0.013-0.120 ng/mL in water. Their recoveries from river water, sea water, sediment and fish samples were 101-132%, 103-145%, 93-166% (except for isoxathion)

and 67-101% (except for isoxathion and phosmet), with R.S.D.s of 1.1-8.0%, 0.9-8.2%, 6.2-28.5% and 4.2-10.8%, resp. [on SciFinder (R)] 0021-9673 organophosphorus/ pesticide/ detn/ environment/ sample

956. Olson, John M., Koenig, Donald F., and Ledbetter, Myron C. (1969). A model of the bacteriochlorophyll-protein from green photosynthetic bacteria. *Archives of Biochemistry and Biophysics* 129: 42-48.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

Crystals of a chlorophyll-protein from Chloropseudomonas ethylicum were studied by X-ray diffraction and electron microscopy. Dimensions of the unit cell (hexagonal space group P63) are a = B = 195 +/- 1 A and c = 98.4 +/- 0.5 A. The unit cell contains six macromolecules (120 chlorophylls). Crystals fixed with glutaraldehyde were sectioned either perpendicular or parallel to the crystal (c) axis and examined in an electron microscope. Sections cut parallel to the crystal axis showed alternate lightdark striations parallel to the axis with a repeat distance of 106 +/- 16 A. Some sections cut perpendicular to the axis showed an hexagonal array of electron-transparent "holes" 120 +/- 20 A apart. The holes and light striations are thought to indicate channels parallel to the c axis at each corner and through the center of each hexagonal unit cell A macromolecular shape approximating a prolate ellipsoid, 88 A long and 65 A in diameter, is consistent with the volume of the macromolecule and crystalline packing considerations. Electron micrographs of negatively stained individual macromolecules indicate an average diameter of 67 +/- 13 A.

A novel approach to calibration is described that involves a single mixt. of pesticides and exploits the advantages of GC-AED. The mixt. has been successfully employed to confirm and quantitate pesticides in a variety of matrixes through elemental ratio calcn. of compd. heteroatoms and element calibrations, resp. The elemental calibration compares favorably with more traditional external and internal calibration techniques. [on SciFinder (R)] 0888-9090 pesticide/ gas/ chromatog/ atomic/ emission

959. Omarov, L. M. (Toxicity of Externally Applied Phthalophos to Rabbits and Cattle. *Tr. Vses. Nauch.-Issled. Inst. Vet. Sanit.35: 200-206; 1970*.
Chem Codes: Chemical of Concern: PSM Rejection Code: NON-ENGLISH.

ABSTRACT: PESTAB The toxicity of cutaneously applied phthalophos (phosmet) suspensions and emulsions in rabbits and cattle was investigated in comparative studies. Spraying with 0. 25-0. 5% emulsions of phthalophos at rates up to 100 mg/kg body weight caused no effects in rabbits, while spraying with 4% and 6% emulsions corresponding to a dose of 320-480 mg/kg produced toxicosis and death. Single sprayings with 2, 3, and 4% phthalophos emulsions, corresponding to doses of 326, 456, and 600 mg/kg, caused toxicosis, while spraying with 6%

emulsion (dose 708-963 mg/kg) also produced cholinesterase inhibition of up to 89% and death. Depending on the doses, varying degrees of hypersalivation, involuntary urination, intensified peristalsis, miosis, motor coordination disorders, anorexia, diarrhea, muscle tremor, lachyrmation, dyspnea, and bradycardia were observed in such animals. Hyperemia of cutaneous vessels, lungs, liver, kidney, brain, and spleen; enlargement of the gallbladder; and hemorrhagic inflammation of the small intenstine were found at autopsy. Spraying cattle once a week with 3 liters of 0. 25-0. 5% emulsion caused no physiological or morphological changes, but it produced cholinesterase inhibition of 9. 5% and 14. 9-32. 5%, respectively.

(GC) anal. of pesticides, the relative retention times (RRT) of 58 pesticides vs. chlorpyrifos were detd. on 8 liq. phases. An RRT diagram was prepd. by plotting the RRT of each pesticide on the horizontal axis and the McReynolds const. on the vertical axis. By using chlorpyrifos as a ref. compd., which has wide sensitivity for several GC detectors, the RRT diagram method was found to be a useful compass for GC anal. These results demonstrated that the RRT diagram could be used to det. the optimal operating conditions for qual. GC anal. of residual pesticides and to know their properties in liq. phase. Thus, the RRT diagram was found to be a very effective tool for confirmation of each pesticide in GC anal. [on SciFinder (R)] 0021-8561 pesticide/ chromatog/ retention/ time/ diagram

A survey was carried out to evaluate levels of pesticide residues in citrus fruits. Two multiresidue anal. methods were used to screen samples for more than 200 different fungicides, insecticides and acaricides. A total of 240 samples of citrus fruits including lemon, orange, mandarin, grapefruit, lime, pomelo and kumquat were taken in various markets in the Geneva area during the year 2003. Ninety-five percent of the 164 samples issued from classical agriculture contained pesticides and 38 different compds. were identified. This high percentage of pos. samples was mainly due to the presence of two post-harvest fungicides, imazalil and thiabendazole, detected in 70% and 36% of samples resp. Only three samples exceeded the Swiss max. residue limits (MRLs). Fifty-three samples sold with the written indication \"without post-harvest treatment\" were also controlled. Among theses samples, 3 exceeded the Swiss MRLs for penconazole or chlorpyrifos and 18 (34%) did not respect the written indication since the authors found large amts. of post-harvest fungicides. Finally, 23 samples coming from certified org. prodn. were analyzed. Among theses samples, three contained small amts. of pesticides and the others were pesticides free. [on SciFinder (R)] 0265-203X

965. Oset-Gasque, M. J., Parram&Oacute, N, M., Gonz&Aacute, and Lez, M. P. (Gabab Receptors Modulate

Catecholamine Secretion in Chromaffin Cells by a Mechanism Involving Cyclic Amp Formation. *Br j pharmacol. 1993, dec; 110(4):1586-92. [British journal of pharmacology]: Br J Pharmacol.* Chem Codes: Chemical of Concern: PSM Rejection Code: IN VITRO.

ABSTRACT: 1. The function of gamma-aminobutyric acidB (GABAB) receptors in modulation of catecholamine secretion by chromaffin cells and the possible mechanism involved in this action have been examined. 2. The GABAB agonists (-)-baclofen and 3-aminopropylphosphinic acid (3-APPA) were found to induce a dose-dependent increase of basal catecholamine secretion. The EC50s were 151 +/- 35 microM and 225 +/- 58 microM for baclofen and 3-APPA, respectively. This stimulatory effect was specific since it could be blocked by 0.5 mM of the specific GABAB antagonist CGP-35348. 3. In contrast, preincubation of chromaffin cells with the GABAB agonists was found to inhibit, in a dose-dependent manner, the catecholamine secretion evoked by 10 microM nicotine and 200 microM muscimol. 4. The effects of GABAB agonists on both basal and evoked catecholamine secretion were found to be accompanied by parallel changes in intracellular calcium concentration ([Ca2+]i). GABAB agonists produced a dose-dependent increase in [Ca2+]i which was partially blocked by CGP 35348, but they produced a strong inhibition of the [Ca2+]i increase induced by nicotine and muscimol. 5. The GABAB agonists also produced a dose-dependent increase in intracellular cyclic AMP levels, there being a direct correlation between both increase in catecholamine secretion and in intracellular cyclic AMP levels. 6. The pretreatment of chromaffin cells with pertussis toxin doubled the catecholamine secretion and increased by four times the intracellular cyclic AMP levels evoked by GABAB agonists. 7. The possible involvement of adenylate cyclase in the mechanism of GABAA receptor modulation of catecholamine secretion is discussed.

966. Oshiro, Yuki and Eylar, E. H. (1969). Physical and chemical studies on glycoproteins : IV. The influence of sialic acid on the conformation of fetuin. *Archives of Biochemistry and Biophysics* 130: 227-234. Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The influence of sialic acid on the conformation of fetuin was investigated by comparing desialized fetuin with untreated fetuin using four different physical chemical techniques. The strong contribution of sialic acid to the acidic properties of fetuin was shown by the rise in the isoionic point from 4.23 to 5.57 for desialized fetuin. Comparison of the titration curves for both the desialized and untreated fetuin revealed that the number of titratable groups in the acidic, neutral, and basic regions agreed with the number expected from the amino acid analysis. The main difference between the two curves was the presence of additional titratable groups in the titration curve of fetuin in the region below pH 4 where the sialic acid carboxyl groups titrate. No evidence was found for the presence of free amino groups of the hexosamine residues, indicating that the amino sugar exists in fetuin as the acetylated derivative. There was no significant difference between the experimental electrostatic interaction factor w, 0.031, whose calculation is based on the carboxyl groups of desialized fetuin, and the experimental value, 0.029. The results

from viscosity studies show that both proteins are fairly compact molecules having a conformation approximated by a prolate ellipsoid of revolution with an axial ratio of 5:1. There was little difference in the intrinsic viscosity of fetuin (5.5 ml/g) and desialized fetuin (5.2 ml/g). These data indicate that no appreciable conformational changes take place on removal of the sialic acid from fetuin. The results from optical rotatory dispersion and circular dichroism studies were inconclusive; at most only a small percentage of secondary structure was indicated. It was concluded that fetuin has a slightly elongated but compact molecular conformation possibly having some secondary structure; removal of the sialic acid does not alter this structure appreciably. http://www.sciencedirect.com/science/article/B6WB5-4DW2F04-RM/2/88f8936778c043ee429689b404cc2aed

967. Ostanin, K. and Van Etten, R. L. (Asp304 of Escherichia Coli Acid Phosphatase Is Involved in Leaving Group Protonation. *J biol chem. 1993, oct 5; 268(28):20778-84. [The journal of biological chemistry]: J Biol Chem*.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

ABSTRACT: Site-directed mutagenesis was used to explore the role of potential proton donors in the mechanism of the Escherichia coli acid phosphatase that is encoded by the appA gene. Asp304 appeared to be the only carboxylic acid residue that is conserved in the protein sequences of the high molecular weight acid phosphatases. The mutations Asp304Ala and Asp304Glu were introduced into appA and the corresponding proteins were overexpressed in E. coli and purified to homogeneity. Only small decreases were observed for the Km values of the substrates p-nitrophenyl phosphate, fructose 1,6-diphosphate, and tripolyphosphate. However, Vmax was greatly decreased, and the magnitude of effect depended markedly on substrate. Both mutant proteins exhibited significantly lower Vmax values with fructose 1,6-diphosphate, which possesses a much poorer leaving group than do the other two substrates. The importance of the leaving group was further tested by using a number of phenyl and alkyl phosphate derivatives as substrates. A linear correlation was observed between log Vmax and the pKa of the substrate leaving group for catalysis by the Asp304Ala mutant enzyme. These results are consistent with partition experiments using ethylene glycol as an alternate nucleophile, which indicated that for the Asp304Ala protein, the formation of a phosphoenzyme intermediate is the rate-determining step, in contrast to the situation for the wild type enzyme and the His303Ala mutant. In the latter case, the rate-limiting step of the reaction is interpreted to be the breakdown of phosphoenzyme. It is concluded that Asp304, rather than His303, is involved in protonation of the substrate leaving group.

ISSN: 0047-2425
Abstract: High rates of N fertilizer in the production of continuous corn (Zea mays L.) have resulted in excessive nitrate N (NO inferior 3-N) leaching, with concentrations in ground water frequently exceeding the maximum contaminant level (MCL) of 10 mg/L. This study was conducted to determine whether NO inferior 3-N leaching would be reduced by allowing for a legume N credit for soybean [Glycine max (L.) Merr.], and applying less N fertilizer to corn in a corn- soybean rotation than would be applied to continuous corn. A rye (Secale cereale L.) winter cover crop was used following soybean. In the spring of each corn year, 140 kg N/ha as NH inferior 4NO inferior 3 was surface applied to two large, undisturbed monolith lysimeters (8.1 m superior 2 surface area, 2.4 m deep), and 196 kg N/ha was applied to two other lysimeters. Prior to 6 yr of this treatment, there was a 6 yr period during which lysimeters received 224 kg N/ha in the spring of the corn year. The highest NO inferior 3-N concentrations and the most transport occurred during the winter/spring soil moisture recharge period (November through April). Concentrations of NO inferior 3-N in the percolate from all four lysimeters were similar, with a 6-yr, flow-weighted average of 9.9 plus-or-minus 2.5 mg/L. Although reducing N fertilizer inputs in a corn-soybean rotation to allow for a legume N credit may lower N leaching amounts and concentrations, the NO inferior 3-N MCL may still be exceeded. For a given year, weather can impact percolation and leaching more than the current crop.

Abstract: Nitrite in natural water was allowed to react with sulphanilamide (SUL) and N-1-naphthylethylenediamine (NED) reagents to form a pink azo dye, which was quantitatively adsorbed onto a Sep-Pak C sub(18) cartridge and was later recovered by eluting with a mixture containing 38% v/v ethanol and 60 mM HCl. The percolate was measured by a spectrophotometer at 543 n. The molar extinction coefficient of the dye in the final solution was found to be 5 x 10 super(4) M super(-1) cm super(-1). Using the proposed manual procedure, nitrite in up to 500 mL of freshwater and 1.5 L of seawater could be concentrated to a final 10 mL with a recovery of >98%. The detection limit was found to be 0.6 nM and 0.2 nM for 500 mL and 1.5 L sizes of sample. A precision of less than 2% at 20-80 nM level could be readily achieved. The cartridge also served for the preservation purpose, as the bound pink azo dye could be stored for up to 4

days without significant change. The proposed manual procedure has been automated by a cycling loop system to suit ship-board determination.

Abstract: This paper presents the purification performance of 20 wastewater treatment plants with vertical reed bed filters (Macrophyltres(registered trademark)), built between 1998 and 2003 by SAS Voisin, for communities of between 150 and 1400 PE. The first stage vertical reed bed (directly fed with raw wastewater by intermittent feeding) achieved high remova of SS, BOD and COD (mean respectively 96%, 98%, 92%). The second stage permitted compliance easily with effluent standards (SS < 15 mg/l, BOD < 15 mg/l, COD < 90 mg/l and mean TKN < 10 mg/l). Performance was not significantly influenced by variations of organic and hydraulic load, nor by seasonal variations. Rigorous operation and maintenance were required to obtain optimal performances. Another application of vertical reed beds is the treatment of septage (sludge from individual septic tanks). The results obtained on two sites operating for 2 and 3 years are presented. The first site achieved complete treatment of septage (solid and liquid fraction), the second permitted a pre-treatment for co-treatment of percolate with wastewater. Citations: Yu, J; Journal of Chromatography A 2004, 1036, 101 A multi-residue method was developed for the detn. of 450 pesticide residues in honey, fruit juice and wine using double-cartridge solid-phase extn. (SPE), gas chromatog.-mass spectrometry (GC-MS) and liq. chromatog.-tandem mass spectrometry (LC-MS-MS). The method development was based on an appraisal of the characteristics of GC-MS and LC-MS-MS for 654 pesticides as well as the efficiency of extn. and purifn. from honey, fruit juice and wine. Samples were first dild. with water plus acetone, then extd. with portions of dichloromethane. The exts. were concd. and cleaned up with graphitized carbon black and aminopropyl cartridges stacked in tandem. Pesticides were eluted with acetonitrile + toluene, and the eluates were concd. For 383 pesticides, the eluate was extd. with hexane twice and internal std. soln. was added prior to GC-MS detn. For 67 pesticides, extn. was with methanol prior to LC-MS-MS detn. The limit of detection for the method was between 1.0 and 300 ng g-1 depending on each pesticide analyte. At the three fortification levels of 2.0-3000 ng g-1, the av. recovery rates were between 59 and 123%, among which 413 pesticides (92% of the 450) had recovery rates of 70-120% and 35 pesticides (8% of the 450) had recovery rates of 59-70%. There were 437 pesticides (97% of the 450) with a relative std. deviation below 25%; there were 13 varieties (3% of the 450) between 25.0 and 30.4%. (GPC) cleanup followed by gas chromatog.-mass spectrometry (GC-MS) and liq. chromatog.-tandem mass spectrometry (LC-MS-MS) has been established for quant. detn. of 437 pesticide residues in animal tissues such as beef, mutton, pork, chicken, and rabbit. Based on an appraisal of the characteristics of both GC-MS and LC-MS-MS, validation expts. were conducted for 660 pesticides. In the method, 10 g animal samples were mixed with 20 g sodium sulfate and extd. with 35 mL of cyclohexane + Et acetate (1 + 1) twice by blender homogenization, centrifugation, and filtration. Evapn. was conducted and an equiv. of 5 g sample was injected into a 400 mm * 25 mm S-X3 GPC column, with cyclohexane + Et acetate (1 + 1) as the mobile phase at a flow rate of 5 mL/min. The 22-40 min fraction was collected for subsequent anal. For the 368 pesticides detd. by GC-MS, the portions collected from GPC were concd. to 0.5 mL and exchanged with 5 mL hexane twice. For the 69 pesticides by LC-MS-MS, the portions collected from GPC were dissolved with acetonitrile + water (60 + 40) after taking the ext. to dryness with nitrogen gas. In the linear range of each pesticide, the correlation coeff. was r >= 0.98, exceptions being dinobuton, linuron, and fenamiphos sulfoxide. At the low, medium and high three fortification levels of 0.2-4800 mg/kg, recoveries fell within 40-120%, among which 417 pesticides recoveries between 60% and 120%, accounting for 95%, 20 analytes between 40% and 60%, accounting for 5%. The relative std. deviation was below 28% for all 437 pesticides. The limits of detection for the method were 0.2-600 mg/kg, depending on each pesticide. Fruit and vegetable samples (20 g) were extd. with 40 mL acetonitrile, salted out, and centrifuged. Half of the supernatant was passed into an Envi-18 cartridge, eluted with acetonitrile, and cleaned up with Envi-Carb and aminopropyl Sep-Pak cartridges in series after concn. of the eluates. Pesticides were eluted with acetonitrile-toluene (3 + 1, vol./vol.), and eluates were concd. to 0.5 mL and then added into internal stds. after solvent exchange with 2 mL hexane and used for detn. of 383 pesticides by GC/MS. The other half of the supernatant was concd. to 1 mL and cleaned up with vegetable and aminopropyl Sep-Pak cartridges in series. Pesticides were eluted with acetonitrile-toluene (3 + 1, vol./vol.), and the eluates were concd. to 0.5 mL, dried with nitrogen gas, dild. to 1.0 mL with acetonitrile-water (3 + 2, vol./vol.), and used for detn. of 63 pesticides by LC/MS/MS. The limit of detection for the method was 0.2-600 ng/g depending on the individual pesticide. In the method, fortification recovery tests at high, medium, and low levels were conducted on 6 varieties of fruits and vegetables, i.e., apples, oranges, grapes, cabbage, tomatoes, and celery, with av. recoveries falling within the range of 55.0-133.8% for 446 pesticides, among which av. recoveries between 60.0-120.0% accounted for 99% of the results. The relative std. deviation was between 2.1-39.1%, of which a relative std. deviation of 2.1-25.0% made up 96% of the results. Expts. proved that the method was applicable for detn. of residues of 446 pesticides in fruit and vegetables. [on SciFinder (R)] 1060-3271 pesticide/ fruit/ vegetable/ extn/ GCMS/ LC/ MSMS

Citations: 46) Mastovska, K; J Chromatogr A 2004, 1040, 259 A new method has been established for simultaneous detn. of 405 pesticide residues in grain, using accelerated solvent extn. (ASE), solid-phase extn. (SPE), and GC-MS and LC-MS-MS. The method was based on appraisal of the GC-MS and LC-MS-MS characteristics of 660 pesticides, their efficiency of extn. from grain, and their purifn. Samples of grain (10 g) were mixed with Celite 545 (10 g) and the mixt. was placed in a 34-mL cell of an accelerated solvent extractor and extd. with acetonitrile in the static state for 3 min with two cycles at 1,500 psig and at 80 DegC. For the 362 pesticides detd. by GC-MS, half of the exts. were cleaned with an Envi-18 cartridge and then further cleaned with Envi-Carb and Sep-Pak NH2 cartridges in series. The pesticides were eluted with acetonitrile-toluene, 3:1, and the eluates were concd. and used for anal. after being exchanged with hexane twice. For the 43 pesticides detd. by LC-MS-MS the other half of the exts. were cleaned with Sep-Pak Alumina N cartridge and further cleaned with Envi-Carb and Sep-Pak NH2 cartridges. Pesticides were eluted with acetonitrile-toluene, 3:1. After evapn. to dryness the eluates were dild. with acetonitrile-water, 3:2, and used for anal. In the linear range of each pesticide the linear correlation coeff. r was equal to or greater than 0.956 and 94% of linear correlation coeffs. were greater than 0.990. At low, medium, and high fortification levels, at the limit of detection (LOD), twice the LOD and ten times LOD, resp., recoveries ranged from 42 to 132%; for 382 pesticides, or 94.32%, recovery was from 60 to 120%. The relative std. deviation (RSD) was always below 38% and was below 30% for 391 pesticides, or 96.54%. The LOD was 0.0005-0.3000 mg kg-1. The proposed method is suitable for detn. of 405 pesticide residues in grain such as maize, wheat, oat, rice, and barley, etc. [on SciFinder (R)] 1618-2642 pesticide/ residue/ contamination/ grain/ GC/ LC/ mass/ spectrometry

Patent Application Country: Application: EP
Priority Application Country: HU
Priority Application Number: 87-5114
Priority Application Date: 19871118 A pesticidal compn. against arthropods comprises pyrethroids, phosphate esters, and optionally piperonyl butoxide and excipients. The pyrethroid is cypermethrin, at 0.1-40% by wt. of the total compn., and comprises 40-100% 1(R),cis(S) and/or 1(R),trans(S) out of the 8 isomers. The 2nd component is phosphoric acid, thiophosphoric acid, or dithiophosphate, at a ratio of 1:(1-99) to cypermethrin. A topical test of Musca domestica was carried out with 100 ng 1(S),trans(R)-cypermethrin and 1000 ng quinalphos in BuOH, which showed a synergistic effect. A compn. was formulated with a 40:60 mixt. of 1(R),cis(S) + 1(S),cis(R)- and 1(R),trans(S) + 1(S),trans(R)-cypermethrin 10, Ca alkylarylsulfonate 35, alkylarylphenol polyglycol ether 80, and quinalphos 400 g in xylene. The emulsion was stable after 24 h in water at a concn. of 0.2 or 5% by wt. [on SciFinder (R)] A01N057-12. A01N057-14; A01N057-16. An automated system appropriate to det. a variety of chem. classes of pesticides and conversion products in water is discussed. This system is based on the online solid-phase extn. (SPE) of target solutes followed by HPLC/tandem photodiode array/post-column derivatization/fluorescence detection

(PDA/PCD/FLD). SPE is performed using a Hysphere-GP (10 * 2 mm) reversed-phase cartridge with the automated PROSPEKT system. Aliquots of 100 mL acidified (pH 3.0) samples are processed. Online HPLC anal. is done using a C18 anal. column eluted with a binary gradient of 10 mM phosphate buffer and an acetonitrile/water (90:10 vol./vol.) mixt. Solutes are tentatively identified by tandem PDA/PCD/FLD. The PDA detector is used as a general purpose detector; the FLD is useful to confirm N-methyl-carbamate and N-methyl-carbamoyloxime pesticides, which are post-column derivatized with o-phthalaldehyde and N,N-dimethyl-2-mercaptoethylamine hydrochloride following hot alk. hydrolysis. The entire anal. system is controlled and monitored with a single computer operated by chromatog. software. Solute recovery from water samples was >80% except for some highly polar and highly hydrophobic compds.; for these compds., resp. recovery was 10-80%. PDA detector-based detection limits were 0.02-0.1 mg/L for the majority of target analytes; detection limits for the PCD/ELD system were 0.005-0.02 mg/L for all amenable analytes. Abstract: Recent evidence from nitrogen (N) saturation studies indicates that forest floors in moderately impacted forests are the primary sink for atmospheric N inputs. Some researchers have suggested that the sink capacity of organic horizons is dependent on the amount of available carbon (C), which can be used for microbial N assimilation. To test the hypothesis that C limitation in forest floors exposed to chronic N deposition leads to an enhanced N leaching, a field C input manipulation experiment is under way in a deciduous forest. Since September 1999 aboveground C input has been doubled (by doubling litter input or by amending glucose) or excluded in replicated plots. Here we report the short-term response of concentrations of dissolved inorganic N (DIN: NO<inf>3</inf>⁻-N and NH<inf>4</inf>⁺-N) in forest floor percolate to the C input manipulation. In autumn following the C input manipulation, DIN concentrations in forest floor percolate decreased in all plots except the No Litter plots compared to the pre-treatment summer concentrations. In contrast, the concentrations of DIN in the No Litter plots remained high. A different seasonal pattern of DIN leaching among treatments, along with measurements of microbial biomass C and potential nitrification rates of forest floor samples, indicates that seasonal N dynamics in the forest floor are largely regulated by C availability changes associated with litterfall C input.

980. Parker, L. V. and Jenkins, T. F. (1986). Removal of trace-level organics by slow-rate land treatment. *Water Research* 20: 1417-1426.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

A 2 yr study was performed on an outdoor, prototype, slow-rate system to determine the removal efficiency for 16 organic substances in wastewater. The 16 organics were chloroform, benzene, toluene, chlorobenzene, bromoform, m-dichlorobenzene, dibromochloromethane, pentane, hexane, nitrobenzene, m-nitrotoluene, diethylphthalate, PCB 1242, napthalene, phenanthrene and pentachlorophenol. The initial concentration of each of these substances in the wastewater was approx. 50 [mu]g l-1. Initial removal was via volatilization during spray application. The final concentration of substances after spraying correlated well with their calculated liquid-phase transfer coefficients and the substances' initial concentration losses were up to 70% for the most volatile components. Total percent removal for the system, based on the residual concentration in the percolate, was >98% for all substances. Only chloroform, which has a low octanol-water partition coefficient and according to the literature is not degraded aerobically, was continuously detected in the percolate. Breakthrough of several other organics in early spring was also observed, apparently as a result of application in late fall. The two substances that were most persistent in the soil were PCB and diethylphthalate (DEP). PCB was retained near the surface while DEP leached deeper in the soil profile as predicted by their respective octanol-water partition coefficients. slow-rate/ land treatment/ wastewater treatment/ trace organics/ toxic organics/ volatilization/ sorption/ biodegradation

ABSTRACT: TD3: The removal efficiency for 16 organic substances in wastewater was studied on an outdoor, prototype slow-infiltration system. The initial concentration of each of these substances in the wastewater was approximately 50 micrograms. Removal was via volatilization during spray application and subsequent adsorption in the soil. The percent removal during spraying could be estimated from the liquid-phase transfer coefficient; losses were up to 70% for the most volatile components. The total percent removal for the system, based on the concentration in the percolate, was more than 98% for all substances. Only chloroform, which has a low octanol-water coefficient and according to the literature is not degradable aerobically, was continuously detected in the percolate. The major final removal mechanisms are believed to be volatilization and biodegradation-biotransformation. Breakthrough of several other organics in early spring as a result of application during the colder months was also observed. The t

The combination of large vol.-difficult matrix introduction (LV-DMI) with gas chromatog.-time of flight-mass spectrometry (GC-TOF-MS), described herein, provides the analyst with a simple but rapid alternative GC-MS technique for the multi-residue anal. of pesticides in fruit-based baby foods. Samples were extd. with Et acetate in the presence of Na2SO4 and NaHCO3 and the crude exts. were analyzed directly using LV-DMI-GC-TOF-MS. The best overall results (98 pesticides quantified satisfactorily at a spiking level of 0.01 mg/kg) were obtained by anal. of concd. exts. (2.5 g crop/mL) using a 30-m column, with a chromatog. run time of 25 min. A good signal-to-noise ratio was obtained at the lowest calibrated level (0.0125 mg/mL), with excellent linearity achieved over the range 0.0125-0.25 mg/mL (equiv. to 0.005-0.1 mg/kg). Av. recoveries for the anal. of 5 replicate detns. at a spiking level of 0.01 mg/kg were between 79 and 114% with relative std. derivations generally <20%. Citations: 21) Erney, D; J Chromatogr A 1994, 638, 57 A rapid method for the screening of organophosphorus (OP) pesticides in fruit and vegetables is reported. Sample exts. were analyzed using resistive heating-gas chromatog. (RH-GC) with flame photometric detection (FPD). A CarboFrit insert in the GC liner allowed injection of crude exts. onto the GC system. Sepn. of up to 20 pesticides was achieved in 4.3 min with excellent retention time stability. Signal-to-noise ratios of 5:1 or better were obtained for the majority of the pesticides at the lowest calibrated level (LCL), 0.01 mg ml-1, with excellent linearity over the range 0.01-0.5 mg ml-1 (0.004-0.2 mg kg-1 equiv.). Av. recoveries between 70 and 116% were obtained for pesticides spiked at 0.01 and 0.1 mg kg-1 with assocd. R.S.D. values ?20% in the majority of cases. Ests. of relative reproducibility std. deviation (R.S.D.R), made by combining obsd. R.S.D. values with ests. of uncertainty assocd. with mean recovery allowed the detn. of HORRAT values which confirmed that the method is capable of producing results which are fit for purpose. The validated method was then used to screen peaches, grapes and sweet peppers for a total of 37 pesticides. Incurred residue results obtained using RH-GC-FPD were in good agreement with the results from anal. of the same samples using MS confirmation. The parameters used for obtaining these correlations are the zero order connectivity, zero order valence mol. connectivity, mol. polarizability, and carbon to hydrogen ratio. The results obtained are satisfactory for environmental applications. Such correlations may be used to predict the logarithm of aq. solubilities (<0.1) and/or the logarithm of the octanol-water partition coeffs. (>-0.4) for pesticides. However, these correlations cannot be used satisfactorily for pesticides having a carbon to hydrogen ratio >=2, or O-analogs. Pesticide parent compds., from a variety of chem. and biol. classes, as well as some of their major conversion products, were included in the target analyte list. Analytes were extd. from 1-l filtered water samples by off-line solid-phase extn. (SPE) on three tandem Sep-Pak C18 cartridges. The sorbed analytes eluted with Et acetate were directly analyzed by gas chromatog.-ion trap mass spectrometry (GC-IT-MS), the mass spectrometer operated in the electron impact (EI) ionization mode. The mean recoveries, at the 0.5 mg/L fortification level, for two-thirds of the analytes ranged from 75 to 120%; the recoveries for less than one third of the analytes ranged from 50 to 75% and the recoveries for the 10 relatively most polar analytes ranged from 12 to 50%. The limit of detection (LOD) of the method for 69 analytes was better than 0.01 mg/L; the LOD for eighteen analytes was better than 0.05 mg/L; for captan, carbofenothion, decamethrin, demeton-S-Me sulfone, fensulfothion, deisopropylatrazine and metamitron, the LOD was 0.1 mg/L and for chloridazon and tetradifon, it was 0.5 mg/L. Identification, in full scan mode, was made at S/N>=3. Quantification, for the majority of the analytes, was made at the base mass. The system was evaluated for monitoring pesticides in surface and ground water samples of Macedonia, Greece. [on SciFinder (R)] 0021-9673 pesticide/ water/ gas/ chromatog/ mass/ spectrometry

Citations: 35) AOAC; Official Methods of Analysis 2nd Supplement to the 15th Ed 1991, 69 A fully automated system for online solid phase extn. (SPE) followed by HPLC with tandem detection with a photodiode array detector and a fluorescence detector (after postcolumn derivatization) was developed for anal. of many chem. classes of pesticides and their major conversion products in aquatic systems. An automated online-SPE system (Prospekt) operated with reversed-phase cartridges (PRP-1) exts. analytes from 100 mL acidified (pH =3) filtered water sample. Online HPLC anal. is performed with a 15-cm C18 anal. column eluted with a mobile phase of phosphate (pH =3)-acetonitrile in 25 min linear gradient mode. Solutes are detected by tandem diode array/derivatization/fluorescence detection. The system is controlled and monitored by a single computer operated with Millennium software. Recoveries of most analytes in samples fortified at 1 mg/L are >90%, with relative std. deviation values of <5%. For a few very polar analytes, mostly N-methylcarbamoyloximes (i.e., aldicarb sulfone, methomyl, and oxamyl), recoveries are <20%. However, for these compds., as well as for the rest of the N-methylcarbamates except for aldicarb sulfoxide and butoxycarboxim, the limits of detection (LODs) are 0.005-0.05 mg/L. LODs for aldicarb sulfoxide and butoxycarboxim are 0.2 and 0.1 mg, resp. LODs for the rest of the analytes except 4-nitrophenol, bentazone, captan, decamethrin, and MCPA are 0.05-0.1 mg/L. LODs for the latter compds. are 0.2-1.0 mg/L. The system can be operated unattended. 989. Peacocke, A. R. and Schachman, H. K. (1954). Studies on the sedimentation behaviour of thymus deoxypentose nucleic acid with reference to its homogeneity, size and shape. *Biochimica et Biophysica Acta* 15: 198-210.
Chem Codes: Chemical of Concern: PSM Rejection Code: MODELING.

1. 1. An examination has been made of the sedimentation and electrophoretic behaviour of separate and mixed solutions of a thymus deoxypentose nucleic acid (DNA) preparation and of the same DNA degraded by sonic irradiation. 2. 2. In sedimentation at an ionic strength of 0.3, the presence of 10% of the degraded DNA in a mixture could be detected, but the method was limited by self-sharpening effects in the boundary and by the insensitivity of sedimentation coefficient (s) to molecular weight. It is concluded that the original DNA cannot contain as much as 10% of such degraded material, but there is some indication of polydispersity in sedimentation at low concentrations. During sedimentation of a mixed solution containing equal amounts of the two DNA's the area of the schlieren peak of the slower, degraded DNA was enhanced by the operation of the Johnston-Ogston effect. 3. 3. In electrophoresis, the individual DNA samples had the same mobility, in spite of the very great difference in the viscosity of their solutions. No separation was observed with the mixtures. 4. 4. Solutions of the degraded DNA (ionic strength = 0.3) had a very much lower viscosity than those of the original DNA and behaved as Newtonian liquids. This enabled its intrinsic viscosity to be determined and a molecular weight for the degraded DNA of the order of 3-4[middle dot]105 was calculated on the basis of different models. 5. 5. The sedimentation data are discussed with reference to the sedimentation of long rod-like] molecules in general. Application of Perrin's equation shows that, for very large axial ratios, s is chiefly dependent on the minor axis of the equivalent prolate ellipsoid. If this model is assumed, the anhydrous diameter of the undegraded DNA molecule in solution can be estimated as 25 A. The data are also discussed in terms of a flexible chain model, and, on that basis, a molecular weight of about 8.5[middle dot]106 is obtained. http://www.sciencedirect.com/science/article/B73G9-47KP99P-5/2/624dd13e0e6a0ad0a43296db5aa746c5

Citations: Webster, E; Environ Toxicol Chem 1998, 17, 2148 A chem.'s ability to persist in the environment is an important criterion in detg. whether concern is warranted. Screening is commonly conducted based on the max. degrdn. half-life of the chem. in any given medium (air, water, soil and sediment), or in terms of model-based ests. of the chem.'s overall persistence (half-life or residence time) in the environment. In practice, however, both approaches are hindered by the limited availability of degrdn. data. Straightforward guidelines are therefore proposed in this paper to help predetermine which half-lives are likely to be pertinent, irresp. of the screening approach adopted. The guidelines are based on partitioning coeffs. (Henry's Law const. and the octanol-water partitioning coeff.). The values selected for use in the guidelines result in a quantifiable trade-off between data acquisition requirements and uncertainty. Initial screening can be performed with whatever data is readily available. Overall persistence predictions will be conservative. False-negatives are not generated. The guideline values can then be adjusted iteratively to facilitate step-wise or tiered screening. Using this iterative approach in national and international screening initiatives will result in significant time and money savings. The theor. possibility that the acute ref. dose (ARD) was being exceeded for a particular pesticide/fruit was tested by applying a combination of maximal variability and max. measured residue relative to an av.-body-wt. consumer. The actual risk was then quantified by stochastically modeling consumption, from dietary survey data, with individual body wts., against published residue results for 2000-2002 and the variability of residue distribution within batches. The results, expressed as nos. of children per day likely to ingest more than the ARD, were in the range of 10-226.6 children per day, depending upon the pesticide and year of sampling. The implications for regulatory action are discussed. [on SciFinder (R)] 1077-3525 pesticide/ pollution/ apple/ pear/ risk/ assessment/ child

Clearly, identification of potential P-gp substrate liability early in the drug discovery process would be advantageous. We describe a multiple-pharmacophore model that can discriminate between substrates and nonsubstrates of P-gp with an accuracy of 63%. The application of this filter allows large virtual libraries to be screened efficiently for compds. less likely to be transported by P-gp. ABSTRACT: The last couple of decades have seen a tremendous increase in interest in the biological properties of natural products as a means to identify novel small compounds that could have potential in clinical medicine. To that end, flavonoids- and flavonoid-like compounds percolate to the top due to their presence in diet constituents and reported beneficial effects on diverse biological processes and disease conditions. As such, the plant polyphenolic antibiotic resveratrol, found in grapes, nuts and wines, has been the focus of many studies aimed at understanding its full range of health beneficial effects. The interest in this compound stems from the earlier observations describing the therapeutic benefits of roots of the oriental medicinal plant from which resveratrol was first isolated. Being a constituent of grapes and wines, the initial work was focused on linking resveratrol to the beneficial cardiovascular effects of moderate wine intake, however, since its reported cancer chemopreventive activity in a murine model of carcinogenesis, there has been a heightened interest in understanding the anti-cancer activity of resveratrol. As a result, a substantial amount of data strongly suggests that resveratrol could affect the process of carcinogenesis through a variety of different mechanisms in different tumor cell types. However, a couple of recent reports provide evidence to the contrary. This critical review attempts to summarize some of these findings and discuss the clinical potential of this compound or its derivatives in the light of the recent conflicting reports.

994. Perveen, A. and Qaiser, M. (2004). Pollen Flora of Pakistan -Xl. Fumariaceae. *Pakistan Journal of Botany, 36 (3) pp. 467-473, 2004*.
Chem Codes: Chemical of Concern: PSM Rejection Code: SURVEY.

ISSN: 0556-3321
Abstract: Pollen morphology of 9 species of the family Fumariaceae from Pakistan has been examined by light and scanning electron microscope. Pollen grains are usually radially symmetrical, isopolar rarely apolar 3-6 colpate occasionally porate, prolate-sub-prolate or oblate-spheroidal rarely suboblate. Sexine thinner or thicker than nexine. Tectum rugulate - fossulate or fossulate-foveolate. On the basis of apertural type, two distinct pollen types are recognized viz., Corydalis diphylla- type and Fumaria indica - type. Playnological data has been useful at generic and specific level.

Chem Codes: Chemical of Concern: PSM Rejection Code: SURVEY.

ISSN: 0556-3321
Abstract: Pollen morphology of 11 species belonging to the genus Cuscuta of the family Cuscutaceae from Pakistan have been examined by light and scanning electron microscope. Cuscutaceae is an eurypalynous family. Pollen grains are generally free, radially symmetrical, isopolar or apolar, colpate, oblate-spheroidal - prolate-spheroidal or sub-prolate rarely spheroidal. Sexine is thicker or as thick as nexine. Tectum reticulate, reticulate rugulate, scabrate or punctate-scabrate. The pollen morphology of the family Cuscutaceae is significantly helpful at specific level. On the basis of exine ornamentation, 3 distinct pollen types viz., Cuscuta reflexa - type, Cuscuta capitata- type and Cuscuta campestris type are recognized.

ISSN: 0556-3321
Abstract: Pollen morphology of 77 species belonging to 36 genera of the family Brassicaceae from Pakistan has been examined by light and scanning electron microscope. Pollen grains are usually radially symmetrical, isopolar sub-prolate to prolate, or prolate-spheroidal rarely oblate-spheroidal, tricolpate rarely 4-8 colpate. Sexine thinner or thicker than nexine. Tectum fine to coarsely reticulate with more or less regular pattern of muri or reticulate - rugulate. On the basis of tectal surface four distinct pollen types are recognized viz., Arabis bijuga-type, Farsetia ramosissima-type, Draba lanceolata -type and Erysimum melicentae - type.

ABSTRACT: Proteomics is more than just generating lists of proteins that increase or decrease in expression as a cause or consequence of pathology. The goal should be to characterize the information flow through the intercellular protein circuitry which communicates with the extracellular microenvironment and then ultimately to the serum/plasma macroenvironment. The nature of this information can be a cause, or a consequence, of disease and toxicity based processes as cascades of reinforcing information percolate through the system and become reflected in changing proteomic information content of the circulation. Serum Proteomic Pattern Diagnostics is a new type of proteomic platform in which patterns of proteomic signatures from high dimensional mass spectrometry data are used as a diagnostic classifier. While this approach has shown tremendous promise in early detection of cancers, detection of drug-induced toxicity may also be possible with this same technology. Analysis of serum from rat models of anthracycline and anthracenedione induced cardiotoxicity indicate the potential clinical utility of diagnostic proteomic patterns where low molecular weight peptides and protein fragments may have higher accuracy than traditional biomarkers of cardiotoxicity such as troponins. These fragments may one day be harvested by circulating nanoparticles designed to absorb, enrich and

amplify the diagnostic biomarker repertoire generated even at the critical initial stages of toxicity.

ABSTRACT: Scientific investigations rept.
ABSTRACT: Prepared in cooperation with Saint Johns River Water Management District, Palatka, FL., Southwest Florida Water Management District, Tallahassee. and Florida State Dept. of Environmental Protection, Tallahassee.
ABSTRACT: The Silver Springs group, in central Marion County, Florida, has a combined average discharge rate of 796 cubic feet per second and forms the headwaters of the Silver River. The springs support a diverse ecosystem and are an important cultural and economic resource. Concentrations of nitrite-plus-nitrate (nitrate-N) in water from the Main Spring increased from less than 0.5 milligrams per liter (mg/L) in the 1960s to about 1.0 mg/L in 2003. The Upper Floridan aquifer supplies the ground water to support spring discharge. This aquifer is at or near land surface in much of the ground-water basin; nutrients leached at land surface can easily percolate downward into the aquifer. Sources of nitrogen in ground water in the Silver Springs basin include atmospheric deposition, fertilizers used by agricultural and urban activities, and human and animal wastes. During 2000-2001, 56 wells in the area contributing recharge to Silver Springs were sampled for major ions, nutrients, and some trace constituents. Selected wells also were sampled for a suite of organic constituents commonly found in domestic and industrial wastewater and for the ratio of nitrogen isotopes (15N/14N) to better understand the sources of nitrate. Wells were selected to be representative of both confined and unconfined conditions of the Upper Floridan aquifer, as well as a variety of land-use types. Data from this study were compared to data collected from 25 wells in 1989-90. Concentrations of nitrate-N in ground water during this study ranged from less than the detection limit of 0.02 to 12 mg/L, with a median of 1.2 mg/L. For data from 1989-90, the range was from less than 0.02 to 3.6 mg/L, with a median of 1.04 mg/L.

Abstract: Monthly fluxes of sulphate (SO<inf>4</inf>²⁻) and base cations (Ca²⁺, Mg²⁺, K⁺) were studied from 1993 to 1996 as precipitation passed through forest vegetation and surface soil layers in an area receiving low and declining levels of atmospheric sulphate pollution. The canopy was dominated by mature Norway spruce (Picea abies Karsten) and the soil was a podzol developed on glacial till material. The mean annual bulk deposition of SO<inf>4</inf>²⁻ collected in the open was 136 mol<inf>c</inf> ha⁻¹ and that of Ca²⁺, Mg²⁺ and K⁺ was 44, 11 and 25 mol<inf>c</inf> ha⁻¹, respectively. The annual total throughfall deposition of SO<inf>4</inf>²⁻ was 318 mol<inf>c</inf> ha⁻¹ and that of Ca²⁺, Mg²⁺ and K⁺ was 151, 64 and 181 mol<inf>c</inf> ha⁻¹, respectively. Sulphate was the dominant anion accompanying the base cations leached from the canopy. More than half (58%) of the annual total throughfall deposition of SO<inf>4</inf>²⁻ was retained by the O-horizon and only 15% leached from below the B-horizon. The annual leaching of Ca²⁺,

Mg²⁺ and K⁺ from below the B-horizon was 14, 25 and 9% of the annual total throughfall deposition, respectively. The transport of base cations through the soil was predominantely countered by SO<inf>4</inf>²⁻ anions.

1006. Pillidge, Christopher J., Collins, Lesley J., Ward, Lawrence J. H., Cantillon, Brenda M., Shaw, Brian D., Timmins, Marie J., Heap, Howard A., and Polzin, Kayla M. (2000). Efficacy of four conjugal lactococcal phage resistance plasmids against phage in commercial Lactococcus lactis subsp. cremoris cheese starter strains. *International Dairy Journal* 10: 617-625.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

The efficacy of four lactococcal phage resistance plasmids (pNP40, pMU1311, pDI60 and pKP100) against phage was assessed after their conjugal transfer to four commercial Lactococcus lactis subsp. cremoris cheese starter strains and to the plasmid-free strain L. lactis subsp. cremoris MG1363. In MG1363, only pNP40 conferred resistance to prolate phages c2 and 643. Highest levels of resistance to small isometric phages in MG1363 occurred when pNP40 was stacked together with pMU1311 or pDI60. In the four starter strains, the plasmids conferred varying levels of resistance to small isometric phages. Growth and acidification rates in milk of most transconjugants derived from the starter strains decreased, but this was not always due to loss of plasmid-encoded cell wall proteinase (lactocepin) activity. Only one transconjugant grew during repeated subculture in milk with addition of factory wheys containing phages. This and the presence of bacteriocins encoded on pMU1311 and pDI60 limited application of the plasmids to protect L. lactis subsp. cremoris starters against phages in industry. However, some of the plasmids could be useful in extending the industry life of starters where fast acid production is not required or where bacteriocin production is acceptable. Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Control of moisture levels in biofilter media is critical to maintaining odor and/or VOC removal performance. Lack of moisture control is perhaps the most common cause of poor biofilter performance and premature media replacement. Moisture control can be provided by a combination of feed gas humidification and application of water to the media surface. When biofilters are used for control of odors in the exhaust air from sludge composting facilities, percolate through the media bed may have elevated levels of nitrate whose impact on groundwater quality should be addressed. The operative factors in design of a moisture control system for an open biofilter are illustrated for a facility where available water is limited and concerns exist over percolate impacts on groundwater.

This method allows the establishment of mol. descriptor/chem. activity relationships by dynamically dividing the descriptor space into a set of fuzzily partitioned subspaces. A set of 153 mol. descriptors was analyzed, including topol., physicochem., quantum mech., constitutional, and electronic parameters, and the most relevant descriptors were selected with the help of a procedure combining genetic algorithm concepts and a stepwise method. The ability of this AFP model to classify the three toxicity classes was validated after dividing the data set compds. into training and test sets, including 165 and 70 mols., resp. The exptl. class was correctly predicted for 76% of the test-set compds. Furthermore, the most toxic class, particularly important for real applications of the toxicity models, was correctly predicted in 86% of cases. Finally, a comparison between the results obtained by AFP and those obtained by other classic classification techniques showed that AFP improved the predictive power of the proposed models. Two multiresidue anal. methods for the simultaneous detn. of organophosphorus and organochlorine pesticides in human urine and serum samples are described. The first approach is based on liq.-liq. microextn. with dichloromethane, and the second uses solid-phase extn. with C18. In both methods, the exts. are analyzed by capillary gas chromatog. using nitrogen-phosphorus detection (NPD) and electron-capture detection (ECD). Limits of detection of the overall procedure of anal. are at the low ng mL-1 level. Stability expts. have been performed with spiked urine and serum samples stored at 4 DegC for 1 mo. Finally, the solid-phase extn. procedure was applied to real-world samples. Quantification was performed by NPD or ECD, and peak identity was confirmed by use of mass-selective detection (MSD). Analytes were isolated by solid-phase extn. using C18 cartridges with subsequent anal. by GC-MS/MS using a glass liner packed with CarboFrit in the GC injection port. Labeled surrogate internal stds. (fenitrothion D6, HCB 13C6,p,p'-DDE D8 and PCB 138 13C12) were added to the samples before the extn. and were used for quantitation and for quality control in the anal. of real-world samples. Accuracy and precision were evaluated by serum samples fortified at 2 concn. levels for the 3 families of compds., with satisfactory results in the majority of cases. The high selectivity and sensitivity of GC-MS/MS allowed low detection limits of 0.05-0.5 ng mL-1 for most of the analytes investigated. The developed procedure improves other current methodologies for the anal. of pesticides and PCBs in biol. fluids, esp. as regards to anal. time and simplicity of sample treatment. The method was applied to several serum samples obtained from farmers devoted to citrus crop prodn. Chlorpyrifos, HCB,p,p'-DDE and the higher chlorinated PCBs (153, 138 and 180) were the most frequently detected compds. Resistance to several of these insecticides in each strain is conferred, in part, by gene(s) on the same autosome as that conferring high oxidase activity. Apparently, a small no. of mutants in the housefly control the level of oxidative metabolism of many insecticides and a portion of the resistance to them. 1013. Podhorniak, L. V., Negron, J. F., and Griffith, F. D. Jr (Gas Chromatography With Pulsed Flame Photometric Detection Multiresidue Method for Organophosphate Pesticide and Metabolite Residues at the Parts-Per-Billion Level in Representatives Commodities of Fruits and Vegetable Crop Groups. *J aoac int. 2001 may-jun; 84(3):873-90. [Journal of aoac international]: J AOAC Int*.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: A gas chromatographic method with a pulsed flame photometric detector (P-FPD) is presented for the analysis of 28 parent organophosphate (OP) pesticides and their OP metabolites. A total of 57 organophosphates were analyzed in 10 representative fruit and vegetable crop groups. The method is based on a judicious selection of known procedures from FDA sources such as the Pesticide Analytical Manual and Laboratory Information Bulletins, combined in a manner to recover the OPs and their metabolite(s) at the part-per-billion (ppb) level. The method uses an acetone extraction with either miniaturized Hydromatrix column partitioning or alternately a miniaturized methylene dichloride liquid-liquid partitioning, followed by solid-phase extraction (SPE) cleanup with graphitized carbon black (GCB) and PSA cartridges. Determination of residues is by programmed temperature capillary column gas chromatography fitted with a P-FPD set in the phosphorus mode. The method is designed so that a set of samples can be prepared in 1 working day for overnight instrumental analysis. The recovery data indicates that a daily column-cutting procedure used in combination with the SPE extract cleanup effectively reduces matrix

enhancement at the ppb level for many organophosphates. The OPs most susceptible to elevated recoveries around or greater than 150%, based on peak area calculations, were trichlorfon, phosmet, and the metabolites of dimethoate, fenamiphos, fenthion, and phorate.

Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Both toxic and mutagenic effect of fosmet as an active component of the organophosphate insecticide Decemtion EK-20 and a solvent mixture was tested on five bacterial strains in S. typhimurium (TA 1535, TA 100, TA 1538, TA 98, TA 97). Within the concentrations ranging from 100 up to 2000 mugetri dish fosmet did not exhibit any toxic effect whereas the solvent mixture used within the range of 2 up to 10 mul/Petri dish was very toxic. Fosmet revealed to be a direct mutagen inducing base substitution (strain TA 100) and frameshift mutations (strain TA 97) on molecular level. Solvent mixture did not exhibit any mutgenic effect on S. typhimurium. Based on the results obtained the authors do not recommend to use Decemtion EK-20 in agricultural practice.

Descriptors: toxicity
Descriptors: Article Taxonomic Terms: Gambierdiscus toxicus
Descriptors: Aedes aegypti
Descriptors: Culicidae
Abstract: A rapid biological method of determining ciguatoxicity (by a mosquito test) is described. An 8 g sample of raw fish is ground up and homogenized in acetone. After centrifugation, the supernatant is concentrated, allowed to percolate through a filter cartridge containing infusorial earth and rapidly chromatographed on silica. The amount of liposoluble residue obtained is 1.0 plus or minus 0.2 mg, irrespective of the fish species and toxicity. The toxicity of the extracts is measured by means of a technique based on the sensitivity of Aedes aegypti mosquitos to ciguatoxin, in which nine batches of ten mosquitos are injected intrathoracically with these extracts at different dilutions.

ABSTRACT: PESTAB. The toxicity of binary mixtures of insecticides [valexon (phoxim), pyrimiphos-methyl, phosalone, phthalophos (phosmet), TsGA 18809, benzophosphate and trichlorfon] with fungicides [zineb, copper chloroxide (copper-oxychloride), polycarbazine and BMC] was studied in houseflies by determining the LC40 during the 24 hr period following

topical application of a benzene solution. The ratio of the insecticide to the fungicide in the mixture was 1:1.25 relative to the active ingredients. The fungicides caused no significant changes in the toxicity of the insecticides. The phytotoxicity of the fungicides was not increased by the insecticides.

ABSTRACT: PESTAB. The development of resistance and cross-resistance was studied in 75 consecutive generations of houseflies exposed to dichlorvos vapors for 20-60 sec or to liquid dichlorvos applied to the skin. The first generation was originally sensitive. The resistance factor, expressed as LD50, increased from 1 in the first generation to 5.1 in F14 and to 6.8 in F75 in the experiments in which dichlorvos vapors were used. The resistance, expressed a the 50% knock-down concentration, rose from 1 to 8.8 in F75. The cross-resistance to chlorophos was 1 in F1, reaching its highest value (> 230) in F35, and declining to > 63 in F75. The flies also developed cross-resistance to diazinon, carbophos (malathion), phthalophos (phosmet), gardona (tetrachlorvinphos), benzophosphate, propoxur, phenetcarb, lindane, fenitrothion, neopinamin (phtaltrin), valaxon (phoxim), permetryne, and Co-Ral (coumaphos). In the experiments in which dichlorvos was applied on the cuticle, the resistance increased from 1 in F1 to 6 in F22 and the cross-resistance to chlorophos (trichlorfon) increased from 1 to 112, respectively, (expressed as LD50).

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Lac repressor and its tryptic core have been investigated by electro-optical methods. The reduced dichroism measured as a function of the electric field strength is not consistent with an induced dipole, but indicates the existence of a strong permanent dipole moment (~ 4 x 10-27 C m) for the holo-repressor, which is almost independent of ion concentration and pH. A dominant contribution of a permanent dipole is also demonstrated by the shape of the dichroism rise curve. The experimental data are not consistent with a counterion polarization phenomenon and also do not indicate a major contribution from proton fluctuations. Probably the nature of the dipole is similar to that found for compounds with a tetrahedral substitution by angular residues. Other potential models involve large conformational fluctuations or inherent asymmetry of the lac repressor. Rotation time constants obtained from the dichroism decay are not consistent with a spherical shape, for either the holo- and or core repressor. A simple interpretation of the data by prolate ellipsoids suggests a short diameter of 6 nm for both holo- and core repressor and long diameters of 14 and 12 nm for holo- and core repressor, respectively. Addition of the inducer isopropyl-[beta]--thiogalactopyranoside leads to a change of the limit dichroism, but does not affect the rotation time constants within experimental accuracy. Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. 8 antioxidants were tested in the SOS chromotest for induction of SOS function and for modulation of benzo(alpha)pyrene-induced SOS

function. None of the antioxidants leads to increased beta-galactosidase activity by itself. Butylated hydroxytoluene at concentrations between 10-5 M and 3t benzo(alpha)pyrene concentrations between 10-6 M and 3 M Butylated hyroxyanisole, ethoxyquin, propyl gallate and octyl gallate also slightly enhance benzo(alpha)pyrene induced SOS function at concentrations up to 3degree than butylated hydroxytoluene. Dodecyl gallate, vitamin C and alpha-tocopherol do not increase benzo(alpha)pyrene action. In concentrations exceeding 3dants tested but not vitamin C and alpha-tocopherol decrease beta-galactosidase activity both in the absence and, more extensively, in the presence of benzo(alpha)pyrene. Preliminary data suggest that the appa suppression of benzo(alpha)pyrene-induced SOS function is not due to an effect on the formation of benzo(alpha)py

1022. Pottinger, R. P. (Keeping Kiwifruit Clean. *N. Z. J. Agric. 141(1): 49-51 1980*.
Chem Codes: Chemical of Concern: PSM Rejection Code: HUMAN HEALTH.

ABSTRACT: PESTAB. Studies are underway to improve the spraying of kiwifruit in order that the growers of the crop will not be deprived of foreign markets due to residue levels of pesticides on their products. Tolerance levels in various countries for gusathion (azinphos-methyl), imidan (phosmet), or benlate (benomyl) are discussed. The levels differ for various countries, but the process used for setting the levels generally involves testing for acute toxicity, short-term effects, genetic mutations, carcinogenic properties, reproductive effects, abnormal growth, biochemical aspects, metabolism and long-term effects in man. Factors which affect the quantity of residues remaining on the crop include application and method, size and surface characteristics of the fruit, pesticide persistence, and residue location. Based on results of studies performed on the kiwifruit, additional fruits are being examined including blackcurrants, blueberries, feijoas, avocados and passionfruit, and apples and boysenberries. As improvement occurs in the management of plant pests, new spraying schedules will be introduced to more effectively meet the residue requirements of various importing countries.

ABSTRACT: Percolate production and precipitation data for a full-scale landfill in operation measured over a 13-year period were used to evaluate the impact and importance of the hydrological conditions of landfill sections on the percolate production rates. Both active (open) and closed landfill sections were included in the evaluation. A simple top cover model requiring a minimum of input data was used to simulate the percolate production as a function of precipitation and landfill section hydrology. The results showed that changes over time in the hydrology of individual landfill sections (such as section closure or plantation of trees on top of closed sections) can change total landfill percolate production by more than 100%; thus, percolate production at an active landfill can be very different from percolate production at the same landfill after closure. Furthermore, plantation of willow on top of closed sections can increase the evapotranspiration rate thereby reducing percolate production rates by up to 47% compared to a grass cover. This process, however, depends upon the availability of water in the top layer, and so the evaporation rate will be less than optimal during the summer where soil-water contents in the top cover are low.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Water with entrained disease-causing virus entering soil normally passes through water-saturated and unsaturated regions before reaching the groundwater. The effects of saturated and unsaturated flow on the survival and transport of a virus, MS-2 bacteriophage, were compared. The viruses were added to well water and applied to soil columns 0.052 m in diameter and 1.05 m long. The soil material was Vint loamy fine sand (a

sandy, mixed, hyperthermic Typic Torrifluvent) mixed with recent alluvium. Samples of the soil water were taken daily at 0.20, 0.40, and 0.80 m depths through porous stainless steel samplers and at 1.05 m from the percolate leaving the column. For saturated flow the virus concentrations reached the influent concentration is less than two pore volumes (PV). From unsaturated flow the concentrations remained at levels much lower than the influent, ranging from 27% of inflow at 0.20 m (18 PV) to 5% at 1.05 m (3.3 PV). At the end of the experiments soil sampl

1026. Prevots, Fabien, Daloyau, Marlene, Bonin, Odile, Dumont, Xavier, and Tolou, Sandrine (1996). Cloning and sequencing of the novel abortive infection gene abiH of Lactococcus lactis ssp. lactis biovar. diacetylactis S94. *FEMS Microbiology Letters* 142: 295-299.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

A gene which encodes resistance by abortive infection (Abi+) to bacteriophage was cloned from Lactococcus lactis ssp. lactis biovar. diacetylactis S94. This gene was found to confer a reduction in efficiency of plating and plaque size for prolate-headed bacteriophage [phi]53 (group I of homology) and total resistance to the small isometric-headed bacteriophage [phi]59 (group III of homology). The cloned gene is predicted to encode a polypeptide of 346 amino acid residues with a deduced molecular mass of 41 455 Da. No homology with any previously described genes was found. A probe was used to determine the presence of this gene in two strains on 31 tested. Lactococcus lactis/ Phage resistance/ Abi http://www.sciencedirect.com/science/article/B6T2W-3W2YG0D-Y/2/89a0ff7ac88a26b82346687f739b4022

Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

Five phage-resistant Lactococcus lactis strains were able to transfer by conjugation the lactose-fermenting ability (Lac+) to a plasmid-free Lac- L. lactis strain. In each case, some Lac+ transconjugants were phage-resistant and contained one or two additional plasmids of high molecular mass, as demonstrated by pulsed-field gel electrophoresis. Plasmids pPF144 (144 kb), pPF107 (107 kb), pPF118 (118 kb), pPF72 (72 kb) and pPF66 (66 kb) were characterized: they are conjugative (Tra+), they confer a phage-resistant phenotype and they bear lactose-fermenting ability (Lactose plasmid) except for the last two. Plasmids pPF144, pPF107 and pPF118 resulted probably from a cointegrate formation between the Lactose plasmid and another plasmid of the donor strain, whereas pPF72, pPF66 and the Lactose plasmid were distinct in the corresponding transconjugants. Plasmids pPF72 and pPF66 produced a bacteriocin. At 30[degree sign]C, the phage resistance conferred by the plasmids was complete against small isometric-headed phage and partial against prolate-headed phage, except for pPF107 whose phage resistance mechanism was totally effective against both types of phages, but was completely inactivated at 40[degree sign]C. Restriction maps of four of the plasmids were constructed using pulsed-field gel electrophoresis. Lactococcus lactis/ Phage resistance/ Plasmids/ Pulsed-field gel electrophoresis http://www.sciencedirect.com/science/article/B6T2W-476W4DG-MB/2/241df429663d674894ae5ddf0ece26e4

Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

A 7.275-kb DNA fragment which encodes resistance by abortive infection (Abi+) to bacteriophage was cloned from Lactococcus lactis subsp. cremoris S114. The genetic determinant for abortive infection was subcloned from this fragment. This gene was found to confer a reduction in efficiency of plating and plaque size for prolate-headed bacteriophage [phi]53 (group I homology) and for small isometric-headed bacteriophage [phi]59 (group III homology). This new gene, termed abiN, is predicted to encode a polypeptide of 178 amino acid residues with a deduced molecular mass of 20[punctuation space]461 Da and an isoelectric point of 4.63. No homology with any previously described genes was found. A probe was used to determine the presence of this gene only in S114 from 31 strains tested. Lactococcus lactis/ Phage resistance/ Abi http://www.sciencedirect.com/science/article/B6T2W-3S2BX18-Y/2/9400f04bc7f15b0cba50068acd1329a6

1029. Price, William S., Nara, Masayuki, and Arata, Yoji (1997). A pulsed field gradient NMR study of the aggregation and hydration of parvalbumin. *Biophysical Chemistry* 65: 179-187.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Pulsed field gradient NMR is a convenient alternative to traditional methods for measuring diffusion of biological macromolecules. In the present study, pulsed field gradient NMR was used to study the effects of calcium binding and hydration on carp parvalbumin. Carp parvalbumin is known to undergo large changes in tertiary structure with calcium loading. The diffusion coefficient is a sensitive guide to changes in molecular shape and in the present study the large changes in tertiary structure were clearly reflected in the measured diffusion coefficient upon calcium loading. The (monomeric) calcium-loaded form had a diffusion coefficient of 1.4 x 10-10 m2 s-1 at 298 K, which conforms with the structure being a nearly spherical prolate ellipsoid from X-ray studies. The calcium-free form had a significantly lower diffusion coefficient of 1.1 x 10-10 m2 s-1. The simplest explanation consistent with the change in diffusion coefficient is that the parvalbumin molecules form dimers upon the removal of Ca2+ at the protein concentration studied (1 mM). ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. As a result of long-term investigations conducted in field stationary experiments, theoretical and practical foundations of regulating effect of farming system elements on weedy component of agrophytocenosis have been worked out. Regularities of variation in its quantitative and qualitative parameters under the effect of long-term (20-25 years) application of soil management systems of different intensiveness, fertilizer, herbicides are deter-mined. The main principles and stages in developing the system of weedy component control (SWCC) are theoretically substantiated. Ecotoxicological evaluation of regular application of herbicides to farm crops is given Agrotechnical and energetic efficiency of minimalization of the ground treatment and presowing soil treatment in crop rotations. of different specialization has been found.

Compulsory exposure of the UK bovine to exclusively high biannual doses of a \"systemic\" pour-on formulation of an organo-phthalimido-phosphorus warblecide, phosmet, during the 1980s (combined with exposure to the lipid-bound residues of \"bioconcd.\" phosmet recycled back via the intensive feeding of meat and bone meal), initiated the \"new strain\" modification of the CNS prion protein (PrP) causing the UK's bovine spongiform encephalopathy (BSE) epidemic. A lipophilic soln. of phosmet was poured along the bovine's spinal column, whence it penetrated and concd. in phospholipids of the CNS membranes, covalently modifying endogenous phosphorylation sites on

phosphatidylinositols (PIs) etc., forming a \"toxic membrane bank\" of abnormally modified lipids that \"infect\" any membrane proteins (such as PrP) that are programmed to conjugate onto them for anchorage to the membrane. Thus, phosmet invokes a primary covalent modification on PrP's PI anchor which, in turn, invokes an overall diverse disturbance upon CNS phosphoinositide second messenger feed back cycle, calcium homeostasis and essential free radicals; thus initiating a self-perpetuating cascade of abnormally phosphorylated PI-PrP that invokes a secondary electrostatic and allosteric disturbance on the main body of PrP impairing tertiary folding. Chaperone stress proteins conjugate onto misfolded PrP blocking its sites of proteolytic cleavage. Fresh epidemiol. evidence is presented and exptl. evidence referenced that adds support to a multifactorial hypothesis which proposes that BSE is a hitherto unrecognized and previously unmanifested class of subtle chronic phosmet-induced delayed neuro-excitotoxicity in the susceptible bovine. ABSTRACT: This paper elucidates the flaws in the official hypothesis that bovine spongioform encephalopathy originated from alterations in the way that scrapie-contaminated cattlefeeds were manufactured in the UK. An alternative hypothesis is proposed that cites exposure of the bovine embryo to various specific high-dose lipophilic formulations of organophosphates, such as the high-dose phthalimide containing organophosphate phosmet, (which were applied compulsorily and exclusively in the UK during the 1980s/early 1990s) as the primary trigger that initiated the deformation of prion protein and the onset of the bovine spongioform encephalopathy epidemic. The multi-site binding metabolites of these organophosphates penetrate the fetus, covalently phosphorylating various active sites on fetal prion protein. The extra charged phosphate groups left on aged prion protein blocks both proteases and chaperones from accessing their catalytic/bonding sites, creating the undergradable, misfolded isoform of prion protein, PrPsc. The resulting abnormally phosphorylated PrPsc aggregates to freshly synthesized PrPc, transforming it into same; due to a system of positive feedback invoked by the organophosphate-induced blockage of a prion protein-specific protein kinase. Both the timing, distribution and dynamics of usage of these specific organophosphates correlates with the epidemiology of bovine spongioform encephalopathy as well as accounting for the 23,000 cattle that have developed the disease, yet were born after the 1988 ban on scrapie-contaminated cattlefeed.

ABSTRACT: For expression of ovine growth hormone (OGH) in inclusion bodies without an affinity histidine tag at either end of the protein, three clones, differing only in the second codon following the ATG start site, were constructed. Their expression was studied by SDS-PAGE followed by immunoblotting. Clone Ala.OGH (clone 1), beginning with Met.Ala.Phe.Pro ellipsis, did not show any expression. Clone Phe.OGH (clone 3), beginning with Met.Phe.Pro ellipsis, gave very high levels of OGH expression following IPTG induction. However, in clone Gly.OGH (clone 2), in which the Ala codon was replaced with a Gly codon at the second position after the start site, a lower level of expression was obtained. Northern hybridization analysis showed that upon IPTG induction, OGH mRNA was transcribed from all three clones. These results therefore, imply that lack of expression in clone 1 and a lower level of expression in clone 2 are not due to a failure of transcription; however, they may be due to inefficient initiation of translation. The secondary structure analysis of mRNA predicts inaccessibility of different elements of the RBS in the case of Ala.OGH (clone 1). The present study highly underscores the importance of mRNA secondary structure at the start site in regulation of expression of a cloned gene in Escherichia coli, a prokaryotic expression system.

1037. Pusch, R. and Kihl, A. (Percolation of Clay Liners of Ash Landfills in Short and Long Time Perspectives. *Waste manag res. 2004, apr; 22(2):71-7. [Waste management & research : the journal of the international solid wastes and public cleansing association, iswa]: Waste Manag Res*.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: Top covers of waste landfills conventionally contain a drain layer over a 1(low-permeable clay liner usually containing smectite minerals. The rate of percolation of the clay liner, which may require tens of years to become water-saturated, determines the downward transport of ions released from the underlying waste to and through the bottom clay liner. The percolation rate is controlled by the composition and density of the tipper liner, which should be as tight as possible. This implies a high density and therefore a high swelling potential which must be moderated by proper design. The bottom clay liner is a less effective and reliable barrier since cation exchange will increase the hydraulic conductivity and cause a significant rise in percolation rate and risk of chemical attack by the percolate. The top liner will undergo very moderate strain if the ash fill is effectively compacted and undergoes little self-compaction. Processes that may cause degradation are freezing and drying and require proper design. In this paper the authors examine the performance of ash-fills isolated by clay liners and conclude that the most important issue is to design and construct the top liner to be as impermeable as possible paying less attention to the tightness of the bottom layer.

Chem Codes: Chemical of Concern: PSM Rejection Code: SURVEY.

ISSN: 0556-3321
Abstract: Pollen morphology of 35 taxa of the family Tamaricaceae from Pakistan has been examined by light and scanning electron microscope. Pollen grains usually radially symmetrical, isopolar prolate-subprolate, rarely prolate-spheroidal, colpate Sexine thinner or thicker than nexine. Tectum reticulate to reticulate - rugulate or foveolate or areolate. On the basis of tectum and relative thickness of sexine and nexine three distinct pollen types are recognized viz., Myricaria squamosa - type, Reaumuria alternifolia - type and Tamarix aphylla - type. Pollen of the genus Tamarix are divided two groups viz., columellae present inside the luminae and luminae

without columellae. Playnological data has been useful at generic and specific level.

Abstract: Quirk and Schofield (1955) in their paper on the effect of electrolyte concentration on soil permeability in relation to sodicity designated 2 concentrations: the threshold concentration, which related to the first discernible effect on soil structure; and the turbidity concentration, at which the dismantling of the soil microstructure is indicated by the appearance of dispersed particles in the percolate - this occurs when the electrolyte concentration is about one-quarter of the threshold concentration. This behaviour is explained in terms of clay domains, which are assemblages of many clay particles in parallel alignment. Within a clay domain, slit-shaped pores with surface separations about equal to the thickness of clay crystals exist. When calcium is the dominant exchangeable ion the clay domains are stable because where contiguous crystals overlap the surfaces reside in a potential well as a result of strong attractive forces. These attractive forces are similar to those responsible for the stability of Camontmorillonite and Ca-vermiculite crystals. A model of 3 clay crystals is used to illustrate how crystal interaction within a clay domain, in terms of classical repulsive diffuse double-layer forces and modern attractive forces, affect domain stability. Attention is drawn to a misconception, now prevalent in the literature, which does not recognise the basic significance of the turbidity concentration with respect to microstructure and wrongly contends that the concentration of electrolyte required to effect the dispersion to flocculation transition in soil suspensions can be used for predicting the level of electrolyte required to sustain soil permeability or infiltration rate in irrigation practice. It is shown that the flocculation concentration is almost 8 times the turbidity concentration. The application of the threshold concentration concept in irrigation practice is discussed. It is demonstrated that the threshold and turbidity concentration comfortably explain the behaviour of a heavy clay soil subjected to border-check irrigation and Cajon sandy loam in Arizona.

The remainder require addnl. descriptors in order to model their toxicity by the QSAR approach. Hence, it has not been possible, to date, to develop common stable QSAR models for the toxicity of diverse chems. with various modes of action on the basis of simple regression relationships. Any new methodol. has to take such different modes of action into account. In our work, we used for this purpose an original combination of the similarity concept and physicochem. descriptors calcd. by HYBOT, in order to construct stable QSAR models of guppy toxicity. The training set comprised 293 diverse chems. Exptl. value(s) of one or more nearest related chems. were used to take structural features and possible modes of toxic action into account. In addn., mol. polarizability and hydrogen bond descriptors for the chems. of interest and related compds. were used to calc. any addnl. contribution in toxicity by means of linear regression relationships. Final comparison of calcd. and exptl. toxicity values gave good results, with std. deviation close to the exptl. error. The compds. were spotted on thin-layer chromatographic sheets, developed in EtOAc-n-hexane, and made visible by exposure to Br vapor followed by spraying with FeCl3 and 2-(o-hydroxyphenyl)benzoxazole. Of the 47 compds. tested, 32 compds. produced fluorescent blue spots under longwave uv light; these consisted of 25 organothiophosphorus pesticides, 5 S-contg. breakdown products, and phosphoric and hypophosphorous acids. A superimposed Congo red spray destroyed the fluorescence and resulted in dark blue spots against a red background. The sensitivity of this method is in the range of 0.2 to 5.0 mg., depending on the specific compd. 27 references. [on SciFinder (R)] 0004-5756

ABSTRACT: TD3: LLNL is developing several innovative remediation technologies as long-term improvements to the current pump and treat approaches to cleaning up contaminated soils and groundwater. These technologies include dynamic underground stripping, in-situ microbial filters, and remediation using bremsstrahlung radiation. Concentrated underground organic contaminant plumes are one of the most prevalent groundwater contamination sources. The solvent or fuel can percolate deep into the earth, often into water-bearing regions. Collecting as a separate, liquid organic phase called dense non-aqueous-phase liquids (DNAPLs), or light NAPLs (LNAPLs), these contaminants provide a source term that continuously compromises surrounding groundwater. This type of spill is one of the most difficult environmental problems to remediate. Attempts to remove such material requires a huge amount of water which must be washed through the system to clean it, requiring decades. Traditional pump and treat approaches have not been

Abstract: The incorporation of the hysteresis effect into the model LEACHP has led to a remarkable improvement in the prediction of herbicide leaching behavior. This modified version uses non-singular and non-linear isotherms for the description of ad- and desorption processes in contrast to the original version that assumes linear adsorption. In most cases of the laboratory studies the hysteresis version calculated less herbicide discharge from the soil profile than the original version. At the same time the modified model showed a much better agreement with the measured data regarding both the herbicide's first appearance in the soil percolate and the location of its maximum concentration. The hysteresis version also calculated less chemical loss under field conditions. The movement of the herbicidal solutes within the soil profile could be identified as highly dependable on large rainfall events.

ABSTRACT: TD3: The Lubbock Land Treatment System Research and Demonstration Project, funded by Congress in 1978 (H.R. 9375), was designed to address the various issues concerning the use of slow rate land application of municipal wastewater. The project involved the (1) physical expansion of an overloaded 40-year old Lubbock slow rate land treatment system; (2) characterization of the chemical, biological and physical conditions of the ground water, soils and crop prior to and during irrigation with secondary treated municipal wastewater; (3) evaluation of the health effects associated with the slow rate land application of secondary effluent and (4) assessment of the effects of hydraulic, nutrient and salt mass loadings on crops, soil and percolate. Percolate investigations, described in the volume, evaluated the fate of infiltrating nutrients from applied wastewaters in the root zone at test plots located on both study farms. Abstract: Enforceable standards play a crucial role in the design and implementation of most water quality policies. The impacts of these standards on farm income and nonpoint source (NPS)

pollution can provide valuable information to develop economic policies that can improve water quality with minimal loss in income and minimal risk. This study uses an integration of nonlinear programming and a simulation model to assess the impacts of enforceable standards at technology and farm boundary levels. The results indicate that the type of pollutant regulated, enforcement type, and the level of standard had a significant impact on farm income and water quality. Choice of farm boundary standards over technology standards is dependent on the impact of the policy on other NPS pollutants, in addition to the reduction of nitrate and phosphorus pollutants. Enforcing farm boundary standards on nitrates had desirable effects on subsurface and percolate nitrogen and variance in income. Technology standards were uncertain in their effects because of the restriction on the choice of technologies available to farmers. A comparative policy analysis considering incentives, multiple impacts, transaction costs of implementation, and regional consideration is important to an effective policy design.

COMMENTS: Update of: Ophthalmology. 1994 Aug;101(8):1347-52 (medline/8058279)
ABSTRACT: BACKGROUND: Vitamins have been reported to be effective in controlling certain types of seizures and to prevent some of the harmful effects of antiepileptic drugs (AEDs). In this review we will summarize evidence from randomized controlled trials. OBJECTIVES: To assess if vitamins improve seizure control, reduce adverse effects of AEDs or improve the quality of life in people with epilepsy. SEARCH STRATEGY: We searched MEDLINE from 1966 to 2004, the Cochrane Epilepsy Group trials register (December 2004), CENTRAL (the Cochrane Controlled Trials Register) (TheCochraneLibrary Issue 4, 2004), and cross-references from identified studies. SELECTION CRITERIA: Randomized or quasi-randomized studies investigating the effects of one or more vitamins given alone or in addition to AEDs to people of any age with any type of epilepsy. DATA COLLECTION AND ANALYSIS: Both reviewers assessed the trials for inclusion and extracted the data. Outcomes assessed included seizure frequency, gingival hyperplasia, neuropathy, changes in bone mineral content, serum calcium, alkaline phosphatase, hemogram, serum levels of AEDs, neuropsychological and quality of life outcomes. Primary analyses were by intention to treat. MAIN RESULTS: Fifteen studies met our inclusion criteria and were of poor methodological quality. None described randomization methods and most enrolled small numbers of participants. Nine studies (331 participants) investigated folic acid. Two studies (75 participants) found no effect for the outcome 50% or greater reduction in seizure frequency (OR 0.96; 95% CI 0.32 to 2.29). Also, no evidence was found for an effect on gingival health, intelligence, behavior, mental health or personality, or measures of red blood volume and hemoglobin content. Folic acid was not associated with any consistent changes in serum phenytoin or phenobarbitone levels or improvement in the mean motor conduction velocities of peripheral nerves. One small study (72 participants) found that thiamine improves neuropsychological functions related to psychomotor speed, visuospatial abilities, selective attention and verbal abstracting ability. One study (226 participants) found a significantly higher bone mineral content (BMC) among patients with epilepsy taking AEDs with vitamin D supplementation compared to controls who were not given supplementation (OR 3.6; 95% CI 2.48 to 4.72; $p < 0.00001$). The studies found no significant effects on serum calcium, alkaline phosphatase or general well-being. One small study (24 participants) found a significant decrease in seizure frequency in those treated

with vitamin E compared to placebo (p = 0.00005; Peto OR 26.73; 95% CI 5.46 to 130.92). AUTHORS' CONCLUSIONS: In view of methodological deficiencies and limited number of individual studies, we have found no reliable evidence to support the routine use of vitamins in patients with epilepsy. Further trials are needed, especially to assess the utility of vitamin D supplementation to prevent osteomalacia and the role of vitamin E on seizures and thiamine in improving cognitive functions.

Citations: Zabik, M; Bulletin of Environmental and Contamination Toxicology 1995, 55, 264 The Canadian Total Diet Study is a national survey to det. the level of chem. contaminants in the Canadian food supply. Food samples were collected from Whitehorse, Yukon, supermarkets as part of the study in 1998. Whitehorse was chosen as a sampling center, despite its small population (n = 19 000), to det. if residue levels were different in foods available in northern communities relative to levels obsd. in previous studies in the more populated south. Foods were prepd. as for consumption before pesticide residue anal. Residue levels obsd. in most foods were similar to levels obsd. in samples from previous surveys from southern Canadian cities. Malathion and DDE (1,1-dichloro-2,2-bis(p-chlorophenyl)ethylene), a transformation product of DDT (1,1,1-trichloro-2,2-bis(p-chlorophenyl)ethane), were the two most frequently detected compds. (26.4 and 25.8%, resp.). The majority of pesticides, however, had a detection frequency of <5%. In general, pesticides in food composites were well below max. residue limits established in the Canadian Food and Drug Regulations. Chlorpropham and captan had the highest dietary intakes (2.16 and 1.94 mg (kg body wt.-day)-1, resp.), based on the results from Whitehorse. No dietary intakes above the acceptable daily intakes, however, were obsd. for any of the 39 pesticides investigated in any age-sex category, where an acceptable daily intake has been proposed. Citations: 10) Vecchia, B; M S Thesis, Colorado School of Mines 1997 In its regulatory role the United States Environmental Protection Agency is the repository for a large collection of dermal absorption data supplied by pesticide registrants. Many of these studies followed a common procedure measuring dermal absorption in vivo into lab. rats as a function of both the amt. of pesticide applied and the exposure time. In this chapter, example registrant data are presented and analyzed. For the 18 pesticides examd. in this study, the relationship between systemic absorption and applied dose was different for pesticides that are liqs. and those that are solids at skin temp. For both groups, the amt. of pesticide in skin increased proportionally with applied dose. Systemic absorption of liq. pesticides also increased with applied dose. However, for solid pesticides systemic absorption was a weaker function of applied dose and in some cases was independent of applied dose. Finally, a simple method for estg. the max. systemic absorption using a pesticide's permeability coeff. and water soly. under-estd. the amt. of dermal absorption for most doses of many of the pesticides investigated in this study. 1057. Regen, David M. (1984). Myocardial stress equations: Fiberstresses of the prolate spheroid. *Journal of Theoretical Biology* 109: 191-215.
<u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: MODELING.

There are occasions in physiological research and medical practice where it is desirable to estimate the average fiberstress in a chamber wall, knowing only the pressure and dimensions. Because the contribution of a strained wall element to pressure depends on its location whereas its contribution to average stress is independent of location, an equation of this kind must involve an assumption about the stress distribution. When applied to a particular chamber, it will give an exact result only if the chamber's stress distribution is in some sense like that of the model for which the equation was derived. Since the fibers of biological chambers are continually being deposited and resorbed, they tend to exhibit similar stretches under the average conditions of the chamber. To the extent that this is so, P = (2/3) [sigma]v ln V0/Vc, is the best simple fiberstress equation for biological chambers. (P = transmural pressure, [sigma]v = volume-averaged fiberstress, V0 = volume enclosed by outside surface, Vc = cavity volume). It expresses the pressure-dimension-average-

fiberstress relation of a chamber of any shape whose stresses exhibit the simplest possible distribution. One can add a term to the right side to account for the influence of stress profile complexities. That term takes the form of a moment whose value is zero at one state of distension. This "stress moment" expresses the unequal weighting of complexities on the two sides of the midwall isobar. Judging from the sarcomere length profile of the left ventricular wall, the stress moment is zero and the average fiberstress equation above is exact for average developed stress (without a second term) when cavity volume is somewhere near end-diastolic. Moreover, the departures from the relation (the effects of stress moment) are small so long as the inner and outer stresses do not differ by a factor greater than two.

1058. Reidys, Christian, Stadler, Peter F., and Schuster, Peter (1997). Generic properties of combinatory maps: Neutral networks of RNA secondary structures. *Bulletin of Mathematical Biology* 59: 339-397.
Chem Codes: Chemical of Concern: PSM Rejection Code: MODELING.

Random graph theory is used to model and analyse the relationships between sequences and secondary structures of RNA molecules, which are understood as mappings from sequence space into shape space. These maps are non-invertible since there are always many orders of magnitude more sequences than structures. Sequences folding into identical structures form neutral networks. A neutral network is embedded in the set of sequences that are compatible with the given structure. Networks are modeled as graphs and constructed by random choice of vertices from the space of compatible sequences. The theory characterizes neutral networks by the mean fraction of neutral neighbors ([lambda]). The networks are connected and percolate sequence space if the fraction of neutral nearest neighbors exceeds a threshold value ([lambda] > [lambda]*). Below threshold ([lambda]<[lambda]*), the networks are partitioned into a largest "giant" component and several smaller components. Structures are classified as "common" or "rare" according to the sizes of their pre-images, i.e. according to the fractions of sequences folding into them. The neutral networks of any pair of two different common structures almost touch each other, and, as expressed by the conjecture of shape space covering sequences folding into almost all common structures, can be found in a small ball of an arbitrary location in sequence space. The results from random graph theory are compared to data obtained by folding large samples of RNA sequences. Differences are explained in terms of specific features of RNA molecular structures.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. The side-effects of agrochemical to Iphiseiodes zuluagai Denmark & Muma (Acari: Phytoseiidae) were studied in laboratory using the residual contact spray method in glass surface. Forty-two plant protection products, used in Brazilian citrus orchards, were tested. Mite mortality and fecundity were evaluated for eight days.

Tested products were ranked in toxicity classes, according to IOBC system, by the total effect (combination of mortality and reproduction effect). The results showed that ca. 26% of the tested products were harmless (captan, clofentezine, fenbutatin oxide, fosetyl, hexythiazox, copper hydroxide, naled, copper oxychloride, cuprous oxide and tetradifon), 14% slightly harmful (abamectin, chlorothalonil, copper sulphate, thiophanatemethyl (PM) and ziram), 7% moderately harmful (sulfur, parathion-methyl and thiophanate-methyl (SC)) and 52% harmful to the mite (acrinathrin, amitraz, azinphos-ethyl, azocyclotin, benomyl, bifenthrin, bromopropylate, carbaryl,

The procedure, based on chromatog. with a short column (30 * 4.6 mm) packed with 3-mm particles, allows 3 times as many samples to be analyzed per unit time as chromatog. with a conventional column (100 * 5.0 mm) with 5-mm particles. This increase in productivity was accomplished with normal operating conditions and std. equipment. There was also a corresponding redn. in solvent vol. Precision, calcd. from peak areas, was <1% relative std. deviation, while the min. detectable amt. of amitraz decreased from 700 to 300 pg. [on SciFinder (R)] 0021-9673 pesticide/ HPLC

1064. Richards, B. K., Steenhuis, T. S., Peverly, J. H., and McBride, M. B. (2000). Effect of sludge-processing mode, soil texture and soil pH on metal mobility in undisturbed soil columns under accelerated loading. *Environmental Pollution* 109: 327-346.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The effect of sludge processing (digested dewatered, pelletized, alkaline-stabilized, composted, and incinerated), soil type and initial soil pH on trace metal mobility was examined using undisturbed soil columns. Soils tested were Hudson silt loam (Glossaquic Hapludalf) and Arkport fine sandy loam (Lamellic Hapludalf), at initial pH levels of 5 and 7. Sludges were applied during four accelerated cropping cycles (215 tons/ha cumulative application for dewatered sludge; equivalent rates for other sludges), followed by four post-application cycles. Also examined (with no sludge applications) were Hudson soil columns from a field site that received a heavy loading of sludge in 1978. Romaine (Lactuca sativa) and oats (Avena sativa) were planted in alternate cycles, with oats later replaced by red clover (Trifolium pratense). Soil columns were watered with synthetic acid rainwater, and percolates were analyzed for trace metals (ICP spectroscopy), electrical conductivity and pH. Percolate metal concentrations varied with sludge and soil treatments. Composted sludge and ash had the lowest overall metal mobilities. Dewatered and pelletized sludge had notable leaching of Ni, Cd and Zn in Arkport soils, especially at low pH. Alkaline-stabilized sludge had the widest range of percolate metals (relatively insensitive to soils) including Cu, Ni, B and Mo. Old site column percolate concentrations showed good agreement with previous field data. Little leaching of P was observed in all cases. Cumulative percolate metal losses for all treatments were low relative to total applied metals. Leachate and soil pH were substantially depressed in dewatered and pelletized sludge soil columns and increased for alkaline-stabilized and ash treatments. Sewage sludge/ Trace metals/ Preferential flow/ Metal mobility/ Leaching http://www.sciencedirect.com/science/article/B6VB5-401RXD1-M/2/a14f6e08a24eb05d136456d313c44d01

1065. Richards, Brian K., Steenhuis, Tammo S., Peverly, John H., and McBride, Murray B. (1998). Metal mobility at an old, heavily loaded sludge application site. *Environmental Pollution* 99: 365-377. Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

This study was undertaken to determine the present distribution and mobility of sludge-applied metals at an old land application site. Trace metals concentrations were determined for soils (using 4 M HNO3 extracts), soil leachates (collected with passive wick lysimeters over a 2.5-year period), and plant tissue from a field site which received a heavy loading of wastewater sludge in 1978 and an adjacent control plot. Blue dye was used to indicate preferential percolate flowpaths in the sludge plot soil for sampling and comparison with bulk soil metals concentrations. After nearly 20 years, metals in the sludge plot leachate were found at significantly greater concentrations than in the control plot, exceeding drinking water standards for Cd, Ni, Zn, and B. Annual metals fluxes were only a fraction of the current soil metal contents, and do not account for the apparent substantial past metals losses determined in a related study. Elevated Cd, Cu, and Ni levels were found in grass growing on the sludge plot. Despite heavy loadings, fine soil texture (silty clay loam) and evidence of past and ongoing metals leaching, examination of the bulk subsoil indicated no statistically significant increases in metals concentrations (even in a calcareous subsoil horizon with elevated pH) when comparing pooled sludge plot soil profiles with controls. Sampling of dyed preferential flow paths in the sludge plot detected only slight increases in several metals. Preferential flow and metal complexation with soluble organics apparently allow leaching without easily detectable readsorption in the subsoil. The lack of significant metal deposition in subsoil may not be reliable evidence for immobility of sludge-applied metals. 1066. Richieri, Gary V., Akeson, Stephen P., and Mel, Howard C. (1985). Measurement of biophysical properties of red blood cells by resistance pulse spectroscopy: volume, shape, surface area, and deformability. *Journal of Biochemical and Biophysical Methods* 11: 117-131. Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

This paper presents a simple, new approach to the determination of size, shape, surface area, and deformability information for cells, notably red blood cells. The results are obtained by combining experimental measurements from resistive pulse spectroscopy (an extension of electronic cell-sizing methodology) with theoretical calculations for model systems. Assuming constancy of surface area and approximating red cell shapes by both prolate and oblate ellipsoids of revolution, values are determined for cell shape factor and volume under a variety of conditions. For red blood cells under low-stress conditions, shape factor, volume, and surface area results are found to be consistent with those available from the literature, when the oblate model is used. Tha applicability of this approach for determination of red cell properties under altered conditions is demonstrated by results for cell volume, at varying osmotic pressure and mechanical shear (tensil) stress. By qunatitating the change in cell shape with stress, a new numerical scale for measuring cell deformability is also obtained, and data are presented on its variation for red cells at different osmolalities, over the range of 140 to 500 mOsm. electronic cell cizing/ erythrocytes/ shape/ surface area/ volume/ deformability http://www.sciencedirect.com/science/article/B6T28-

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: TD3: In three deciduous forests with soils classified as sensitive to acid rain, soil chemistry and nutrient cycling were examined to evaluate effects of acid precipitation on soil acidity, leaching, and supplies of base cations. Results indicated that strong acidity in precipitation (pH 4.3 to 4.4 to 0.6 keg ha exp -1 year exp -1) is rapidly neutralized by canopies and forest floors, before rainwater percolates beyond surficial layers of forest soil. Annual natural acid production exceeded H exp + -ion inputs in acid precipitation by at least 2.8 times at a study site where estimates were made of HCO sub 3- leaching and ion accumulation in aboveground biomass. The pH of solutions throughout soil profiles averaged 5.4 to 6.0, indicating that forest soils serve as sinks of enormous capacity for H exp + -ions of external and internal origin. In the surface 50 to 80 cm of oil, exchangeable base cations that are immediately available for plant uptake are more than two orders of magnitude greater than an

Citations: 37) Dejonckheere, W; J AOAC Int 1996, 79, 97 For the 5-yr period 1991 to 1995, 1536 vegetable and 802 fruit samples were analyzed. The purpose of this study was to det. if pesticides were present on Ontario-produced fruits and vegetables, and if so, to det. if residues violated max. residue limits (MRLs). Overall, 31.5% of the samples had no detectable pesticide residues, whereas 68.5% contained one or more residues. Most of the residues were present at very low concns.; 48% of the detections were <0.1 ppm (ppm), and 86% were <1 ppm. However, violations of MRL were obsd. in only 3.2% of the vegetable samples and 3.1% of the fruit samples. In addn., 4.8% of the samples contained a \"tech.\" violation, i.e., there was no specified MRL for the pesticide-commodity combination and the residues exceeded 0.1 ppm. Of the detectable residues, 63% were <10% of the MRL, whereas 89% were <50% of the MRL. More fruit samples (91.4%) had a detectable residue, compared with vegetable samples (56.6%). Fruit is often treated close to harvest or post harvest to ensure that wholesome produce reaches the consumer. Forty-six percent of the samples contained 2 or more residues, and 2% of all samples had more than 5 different pesticides detected; fruit samples tended to have more multiple residues. The most frequently found pesticides were captan, the dithiocarbamate fungicides, endosulfan, azinphos-Me, phosmet, parathion, and iprodione. These pesticides were also used in the greatest quantity for crop prodn. Overall, the data agree fairly closely with those reported for the U.S. Department of Agriculture Pesticide Data Program because the 2 programs have similar anal. goals and objectives. A gas chromatog. method was developed for the detn. of 14 organophosphorus insecticides in natural waters at <1 ppb. Using C_6H_6, extn., recoveries were 95-110% for 13 compds., and av. 115% for Ruelene (crufomate)(I) [299-86-5]. Isothermal gas-liq. chromatog. used 11% (wt./wt.) OV-17/QF-1 on 80-100 mesh Chromosorb Q at 200 Deg with 80 ml N/min as the carrier and 150 ml H, 20 ml O, and 10 ml air/min for the dual flame photometric detector. The detection limit ranged from 0.005 ppb for Thimet (phorate) [298-02-2] and Di-Syston (disulfoton) [298-04-4] to 0.10 ppb for Imidan [732-11-6], Guthion (azinphosmethyl) [86-50-0], and Ethyl Guthion (azinphosethyl) [2642-71-9]. ABSTRACT: TD3: Research has continued at a low-level waste disposal facility to characterize the physicochemical species of radionuclides migrating in groundwater. This facility consists of an unlined basin and connecting trench which receives effluent water containing low levels of a wide variety of fission and activation products and trace amounts of transuranic radionuclides. The effluent water percolates through the soil and a small fraction of it emerges at seepage springs located some 260 meters from the trench. The disposal basin and trench are very efficient in retaining most of the radionuclides, but trace amounts of a number of radionuclides existing in mobile chemical forms migrate in the groundwater from the trench to the springs. This facility provides the opportunity for characterizing the rates and mechanisms of radionuclide migration in groundwaters, identifying retardation processes, and validating geochemical models.

Citations: Weeks, A; Journal of Economic Entomology 2000, 93, 1183 Earth mites are pests of crops and pastures in southeastern Australia. Recent studies show differences between earth mite species in their mode of reprodn., preferred hosts and pesticide tolerance. The distribution and pest status of each species was examd. The southeastern Australian distribution for each species was mapped, incorporating new data from eastern New South Wales, South Australia and Tasmania. A new population of an undescribed species previously identified from northwestern Victoria was found in northern New South Wales. CLIMEX was used to identify climatic factors limiting the distribution of P. major and P. falcatus, the most broadly distributed species. This anal. suggests tolerance to heat and desiccation limits the inland distribution of these two species. A three-year survey of agricultural outbreaks indicates that all Penthaleus species are major agricultural pests although their pest status on crop types appears to differ. All species contributed to chem. control failures. However P. falcatus, previously identified in lab. tests as having increased tolerance to pesticides, was the most common species assocd. with control failures. A

lab. expt. indicated that mites are sometimes pests on crops on which they cannot persist for a generation. Results are discussed with respect to management of these agricultural pests. [on SciFinder (R)] 0168-8162 Penthaleus/ Halotydeus/ distribution/ pesticide/ resistance/ Australia

In order to evaluate the impact of pesticides in the Lisbon drinking water supply system, following the requirements of the European Union Directive 98/83/EC, we developed and validated an anal. method based on the combination of solid-phase extn. with liq. chromatog. and tandem mass spectrometry. In this work, several pesticides were studied: imidacloprid, dimethoate, cymoxanil, carbendazime, phosmet, carbofuran, isoproturon, diuron, methidathion, linuron, pyrimethanil, methiocarb, tebuconazole and chlorpyrifos. Several parameters of the electrospray source were optimized in order to get the best formation conditions of the precursor ion for each pesticide, namely capillary and extractor voltage, cone voltage, cone gas flow rate and desolvation gas flow rate. After optimization of the collision cell energy of the triple quadrupole, two different precursor ion - product ion transitions were selected for each pesticide, one for quantification and one for qualification, and these ions were monitored under time-scheduled multiple reaction monitoring (MRM) conditions. The selection of specific fragment ions for each pesticide guarantees a high degree of selectivity as well as addnl. sensitivity to quantify trace levels of these pesticides in water samples. This method showed excellent linearity ranges for all pesticides, with correlation coeffs. greater than 0.9989. Detn. limits (between 0.0041 and 0.0480 mg/L), precision (RSD <9.18%), accuracy and recovery studies in several water samples using solid-phase extn. were also performed. 1076. Rodriguez, E., Wood, Z. A., Karplus, P. A., and Lei, X. G. (Site-Directed Mutagenesis Improves Catalytic Efficiency and Thermostability of Escherichia Coli Ph 2.5 Acid Phosphatase/Phytase Expressed in Pichia Pastoris. *Arch biochem biophys. 2000, oct 1; 382(1):105-12. [Archives of biochemistry and biophysics]: Arch Biochem Biophys*.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

ABSTRACT: Escherichia coli pH 2.5 acid phosphatase gene (appA) and three mutants were expressed in Pichia pastoris to assess the effect of strategic mutations or deletion on the enzyme (EcAP) biochemical properties. Mutants A131N/ V134N/D207N/S211N, C200N/D207N/S211N, and A131N/ V134N/C200N/D207N/S211N had four, two, and four additional potential N-glycosylation sites, respectively. Extracellular phytase and acid phosphatase activities were produced by these mutants and the intact enzyme r-AppA. The N-glycosylation level was higher

in mutants A131N/V134N/D207N/S211N (48%) and A131N/V134N/ C200N/D207N/S211N (89%) than that in r-AppA (14%). Despite no enhancement of glycosylation, mutant C200N/ D207N/S211N was different from r-AppA in the following properties. First, it was more active at pH 3.5-5.5. Second, it retained more (P < 0.01) phytase activity than that of r-AppA. Third, its specific activity of phytase was 54% higher. Lastly, its apparent catalytic efficiency kcat/Km for either p-nitrophenyl phosphate (5.8 x 10(5) vs 2.0 x 10(5) min(-1) M(-1)) or sodium phytate (6.9 x 10(6) vs 1.1 x 10(6) min(-1) M(-1)) was improved by factors of 1.9- and 5.3-fold, respectively. Based on the recently published E. coli phytase crystal structure, substitution of C200N in mutant C200N/D207N/S211N seems to eliminate the disulfide bond between the G helix and the GH loop in the alpha-domain of the protein. This change may modulate the domain flexibility and thereby the catalytic efficiency and thermostability of the enzyme.

1077. Romero, E. , Sanchez-Rasero, F., Pena, A., De, L. A. Colina C, and Dios, G. (1996). Bentazone Leaching in Spanish Soils. *Pesticide science* 47: 7-15.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Adsorption, incubation and soil-column experiments with bentazone (3-isopropyl-1H-2,1,3-benzothiadiazin-4(3H)-one 2,2-dioxide) were carried out in ten different soils from the marches surrounding the Donana National Park (Huelva, SW Spain). Adsorption isotherms for the different soils showed a good fit with the Freundlich equation. Bentazone was poorly adsorbed in all the soils studied, with no significant relationship between the Kf values and soil characteristics. A significant correlation was obtained between the soil organic matter content and the distribution constant values (Kd) calculated at an equilibrium concentration of 200 mug cm-3. The low adsorption and non-degradation of bentazone on these soils suggest that the herbicide readily percolates through soils to reach the surface and ground waters. The mobility of bentazone through three soil columns was also studied. The mass balances carried out showed that bentazone was totally eluted from the soil columns.

Abstract: Deuterium-labeled water was used to study the effect of the Tapajo(acute)s Throughfall Exclusion Experiment (TTEE) on soil moisture movement and on depth of water uptake by trees of Coussarea racemosa, Sclerolobium chrysophyllum, and Eschweilera pedicellata. The TTEE simulates an extended dry season in an eastern Amazonian rainforest, a plausible scenario if the El Nin(tilde)o phenomenon changes with climate change. The TTEE excludes 60% of the wet season throughfall from a 1-ha plot (treatment), while the control 1-ha plot receives precipitation year-round. Mean percolation rate of the label peak in the control plot was greater than in the treatment plot during the wet season (0.75 vs. 0.07 m/mo). The rate was similar for both plots during the dry season (ca. 0.15 m/mo), indicative that both plots have similar topsoil structure. Interestingly, the label peak in the control plot during the dry season migrated upward an average distance of 64 cm. We show that water probably moved upward through soil pores - i.e., it did not involve roots (hydraulic lift) - most likely because of a favorable gradient of total (matric + gravitational) potential coupled with sufficient unsaturated hydraulic conductivity. Water probably also moved upward in the treatment plot, but was not detectable; the label in this plot did not percolate below 1 m or beyond the depth of plant water uptake. During the dry season, trees in the rainfall exclusion plot, regardless of species, consistently absorbed water significantly deeper, but never below 1.5-2 m, than trees in the control plot, and therefore may represent expected root function of this understory/subcanopy tree community during extended dry periods.

Market samples of various vegetables were analyzed for organophosphorus pesticides by capillary column gas chromatog. and a flame-photometric or thermionic detector. Some crops, like celery, mushroom, and carrot do not show interferences with either of these detectors; for cabbage samples the flame-photometric detector is to be preferred and for onion and leek the thermionic detector shows the least interferences. For the anal. of relatively volatile organophosphorus compds. in cabbage, onion, and leek a clean-up of the ext. is advisable, and such a method, using reversed phase liq. chromatog., was developed. Out of 135 samples, 21 contained detectable residues of organophosphorus compds.; in 2 samples the tolerance limit was exceeded. Diazinon [333-41-5] and trichloronate [327-98-0] were the most frequently detected compds., esp. in carrots. In 10 out of 20 carrot samples diazinon could be detected and in 5 out of 20 carrot samples trichloronate was found. 1083. Ross, C. T. F. and Etheridge, J. (2000). The buckling and vibration of tube-stiffened axisymmetric shells under external hydrostatic pressure. *Ocean Engineering* 27: 1373-1390.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The paper reports on a theoretical and an experimental investigation into the buckling and vibration of prolate hemi-ellipsoidal tube-stiffened domes under external water pressure. The theoretical analyses were via the finite element method, where both the fluid and the structure were modelled with finite elements. The dome was modelled with a varying meridional curvature element and with eight displacement degrees of freedom and the water was modelled by solid annular elements where each element had eight pressure degrees of freedom in its cross-section. Comparison was good between experiment and theory. Shells/ External pressure/ Buckling/ Vibration/ Tube-stiffened http://www.sciencedirect.com/science/article/B6V4F-40GJDMT-5/2/c496101c63e4216194bfa94931e53f41

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The paper reports on a theoretical and an experimental investigation carried out on a thin-walled hemi-ellipsoidal prolate dome in air and also under external water pressure. The investigation found that there was good correlation between experiment and theory. The theoretical investigation was carried out using the finite element analysis to model both the structure and the fluid. The theoretical investigation used two different programs, one of which was the giant computer program ANSYS and the other was an in-house program developed by Ross. For the shell structure, the ANSYS program used 2 different doubly curved thin-walled shell elements, while the in-house program used a simpler axisymmetric thin-walled shell element. This axisymmetric element allowed a sinusoidal variation of the displacements in the circumferential direction, thus, decreasing preparation and computational time. Agreement between the 3 different finite elements was found to be good. This was found particularly encouraging for the in-house software, as it only took a few hours to set up the computer model, and a few seconds to analyse the vessel, whereas the ANSYS software took several weeks to set up the computer model, and several minutes to analyse the shell dome. The ANSYS software, however, did have the advantage in producing excellent graphical displays in both the pre-processing and post-processing modes. Vibration/ Thin-walled shells/ Domes/ Finite elements/ Water pressure/ ANSYS http://www.sciencedirect.com/science/article/B6V4F-4K7FJSW-3/2/d43b898692c33a3ba98b99176da04ece

1085. Ross, Carl T. F., Little, Andrew P. F., and Bartlett, Colin (2004). The vibration of a large ring-stiffened prolate dome under external water pressure. *Ocean Engineering* 31: 1-19.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The paper presents a theoretical and an experimental investigation into the free vibration of a large ring-stiffened prolate dome in air and under external water pressure. The theoretical investigation was via the finite element method where a solid fluid mesh with an isoparametric cross-section was used to model the water surrounding the dome, and a truncated conical shell and ring stiffener were used to model the structure. Good agreement was found between theory and experiment. Both the theory and the experiment found that as the external water pressure was increased the resonant frequencies decreased. Vibration/ Water pressure/ Finite elements/ Ring-stiffeners/ Dome/ Submarine http://www.sciencedirect.com/science/article/B6V4F-49YCWYS-1/2/582732800a3d7f59aec63e3a100ed2e5

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The paper reports on the buckling of three ring-stiffened prolate domes under external hydrostatic pressure. The study was partly theoretical and partly experimental, where in the case of the latter, the finite element was used. Comparison between experiment and theory was good. The effect of ring stiffening the domes was to increase their buckling resistances by factors varying from 4.43 to 5.72. (GC) and gel permeation chromatog. (GPC) clean-up is described. Freeze-dried or lyophilized insect samples were blended with diatomaceous earth (Extrelut) then underwent elution with methylene chloride. This extn. method has shown good recovery on various spike std. levels. Samples are cleaned up by GPC with a Bio Beads SX 3 column and a cyclohexane-ethylacetate (1:1) eluant. Organophosphorus and carbamate compds. are quantified using capillary gas chromatog. Good linearity ranges were obsd. for all compds. The extn. process was rapid and results were good, despite the complexity of the matrix on which it was applied. It allowed a redn. both in cost and the consumption of solvents, thereby safeguarding the health of the analyst and the environment. Environmental monitoring using bees was confirmed to be a valid procedure. [on SciFinder (R)] 0021-9673 pesticide/ honeybee/ gas/ chromatog/ pollution/ monitor

Citations: Wessels, D; Environ Health Perspect 2003, 111, 1939 Our understanding of the health risks of farmworkers exposed to pesticides in their work and home environments is rapidly increasing, although studies designed to examine the possible neurobehavioral effects of low-level chronic pesticide exposure are limited. We measured dialkyl phosphate urinary metabolite levels, collected environmental dust samples from a subset of homes, obtained information on work practices, and conducted neurobehavioral tests on a sample of farmworkers in Oregon. Significant correlations between urinary Me metabolite levels and total Me organophosphate (azinphos-Me, phosmet, malathion) house dust levels were obsd. We found the neurobehavioral performance of Hispanic immigrant farmworkers to be lower than that obsd. in a nonagricultural Hispanic immigrant population, and within the sample of agricultural workers there was a pos. correlation between urinary organophosphate metabolite levels and poorer performance on some neurobehavioral tests. These findings add to an increasing body of evidence of the assocn. between low levels of pesticide exposure and deficits in neurobehavioral performance. 1091. Roux, K. H., Dhanarajan, P., Gottschalk, V., Mccormack, W. T., and Renshaw, R. W. (1991). Latent A1 Vh Germline Genes in an A2a2 Rabbit: Evidence for Gene Conversion at Both the Germline and Somatic Levels. *J immunol* 146: 2027-2036.
Chem Codes: Chemical of Concern: PSM Rejection Code: IN VITRO.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. We have previously reported the sequences of putative latent a1 cDNA derived from an a2a2 rabbit. Significant similarity to nominal a1 cDNA sequences was noted, but none of the latent sequences were completely a1-like. We have now probed a genomic library, produced from the same a2a2 rabbit, for evidence of germline latent a1 VH genes. Four hundred ninety-four VH+ clones were screened with oligonucleotides specific for a1 diagnostic regions of framework region 1 (FR1) and FR3. Twenty-two percent of the VH+

clones hybridized with an a1FR3 oligonucleotide probe. Two a1 FR1 probes yielded weak signals with 6% to 13% of the VH+ clones. Twenty VH genes from clones positive for one or more of the a1-specific oligonucleotide probes were sequences, revealing 14 unique germline VH genes. All but one of these genes were 85% to 92% identical to the VH1-a1 normal gene prototype, with sequence identity extending into the leader intron. Most genes displayed extended regions of simila

based study of pesticide residues in domestic and imported pears and tomatoes. For pears, 710 domestic and 949 imported samples were collected and analyzed; 79% of the domestic and 72 of the imported samples had detectable residues. Thiabendazole, a fungicide with postharvest uses, was found with greatest frequency in both groups of pears. Four domestic and 12 imported samples contained violative residues, mainly of pesticides for which there are no U.S. tolerances on pears. The statically weighted (by shipment size) violation rates for domestic and imported pears were 1.0 and 0.9%, resp. For tomatoes, 1219 domestic and 144 imported samples were collected and analyzed; 84% of the domestic and 91% of the imported samples had detectable residues. Methamidophos, an insecticide, had the greatest frequency of occurrence in both groups of tomatoes. Thirty-three domestic and 5 imported samples were violative, nearly all the result of acephate use, for which there is no U.S. tolerance on tomatoes. The statistically weighted violation rates for domestic and imported tomatoes were 1.9 and 7.0%, resp. The statistically weighted violation rates calcd. for domestic and imported pears and domestic tomatoes in this study were lower than those obsd. under FDA's regulatory monitoring in recent years. The violation rate for imported tomatoes was somewhat higher under statistical monitoring than under regulatory monitoring. The results of the statistically based study show that, as in regulatory monitoring, the levels of pesticide residues found are generally well below U.S. tolerances. For apples, 769 domestic and 1062 imported samples were collected and analyzed; 85% of the domestic and 86% of the imported samples had detectable residues. Benomyl, a widely used fungicide, was found with greatest frequency in domestic apples, while diphenylamine was found most often in imported apples. One domestic and 4 imported samples contained violative residues of pesticides for which there are no U.S. tolerances on apples. The statistically weighted (by domestic packer throughput or import shipment size) violation rates for domestic and imported apples were 0.30% (0.13 unweighted) and 0.41% (0.38 unweighted), resp. For rice, 598 domestic and 612 imported samples were collected and analyzed; 56% of the domestic and 12% of the imported samples had detectable residues. Malathion had the greatest frequency of occurrence in both groups of rice. Eight domestic and 9 imported samples were violative, all as a result of use of pesticides for which there are no U.S. tolerances on rice. The statistically weighted violation rates for domestic and imported rice were 0.43% (1.3 unweighted) and 1.1% (1.5 unweighted), resp. Results of the statistically based study show that, as in FDA's regulatory monitoring, the levels of most pesticide residues found in these 2 commodities are generally well below U.S. tolerances, and few violative residues are found. Citations: Kifs; Kemikalieinspektionens forfattningssamling 2001, 3 The European Commission has decided on harmonized classifications for a large no. of individual chems. according to its own directive for classification and labeling of dangerous substances. The authors have compared the harmonized classifications for acute oral toxicity to the acute oral toxicity data available in the RTECS database. Of the 992 substances eligible for this comparison, 15% were assigned a too low danger class and 8% a too high danger class according to the RTECS data. Due to insufficient transparency-scientific documentations of the classification decisions are not available-the causes of this discrepancy can only be hypothesized. It is proposed that the scientific motivations of future classifications be published and that the apparent over- and underclassifications in the present system be either explained or rectified, according to what are the facts in the matter. 1096. Rueegg, Willy Thaddaeus, Urwiler, Michael Joseph, and Clemens, Christoplher Glen (20050616). Herbicidal combinations comprising a HPPD-inhibiting herbicide and an insecticide. 48 pp.
Chem Codes: Chemical of Concern: PSM Rejection Code: PATENT.

Copyright: Copyright (C) 2007 ACS on SciFinder (R))
Database: CAPLUS
Accession Number: AN 2005:523211
Chemical Abstracts Number: CAN 143:39502
Section Code: 5-3
Section Title: Agrochemical Bioregulators
Coden: PIXXD2
Index Terms: Herbicides; Insecticides (herbicidal combinations comprising a HPPD-inhibiting herbicide and an insecticide); Bacillus sphaericus; Bacillus thuringiensis; Schoenocaulon (mixts. with HPPD-inhibiting herbicides; herbicidal combinations); Petroleum; Pyrethrins Role: AGR (Agricultural use), BIOL (Biological study), USES (Uses) (mixts. with HPPD-inhibiting herbicides; herbicidal combinations); Toxins Role: AGR (Agricultural use), BIOL (Biological study), USES (Uses) (d-endotoxins, mixts. with HPPD-inhibiting herbicides; herbicidal combinations)

[Effect of Excitant Amino Acid Antagonists on Glutamate Receptors in the Locust and on Convulsions Induced by Glutamate, Aspartate, Kynurenine and Quinolinic Acid in Mice]. *Biull Eksp Biol Med* 101: 322-325.
Chem Codes: Chemical of Concern: PSM Rejection Code: NON-ENGLISH.

ABSTRACT: All excitatory amino acid antagonists studied: diethyl esters of aspartic (DEEA) and glutamic (DEEG) acids, 2-amino-3-phosphono-propionic acid (APPA) and 2-amino-4-phosphono-butanoic acid (APBA), diminished the amplitude of excitatory postsynaptic potentials (EPP) of the locust (Locusta migratoria migratorioides) muscle fibers and arbitrary blocked glutamate (GLU) and aspartate (ASP) responses. Kynurenine (KYN) and quinolinic (QUI) acid had no effect on EPP even at a concentration of 2 X 10(-2) M. The antagonists were not strictly selective against intracerebroventricularly administered endogenous convulsants: GLU, ASP, KYN and QUI and in simulation of experimental seizures in mice. The antagonists structurally similar to ASP prevented ASP- and KYN-induced seizures in lower doses than GLU derivatives. Anti-KYN, but not anti-QUI DEEA, DEEG, APPA and APBA efficacy suggests that KYN and QUI act on different structures or binding sites.

1098. Saavedra-P, J. (1989). Anthonomus Vestitus in Piura, Peru: Its Susceptibility to Insecticides Tested in Laboratory. *Rev peru entomol* 32: 43-46.
Chem Codes: Chemical of Concern: PSM Rejection Code: NON-ENGLISH.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. The main interest of this work was to find an insecticide with an inmediate lethal action and a short-period effect against "Peruvian cotton square-weevil", in order to use it in monitoring this insect in mesquite or "algarrobo" (Prosopis spp.) natural vegetation; and besides, to know the efficience of other products actually used to control this pest in Piura valleys. - Adults of Anthonomus vestitus Bohemann, obtained from a laboratory masal rearing were used. To test the inmediate lethal action the insecticides were

distributed on the inner part of petri dishes where the weevils were introduced and maintained inside during 5, 10 and 20 minutes. To probe the residual effect, other weevils were introduced into petri dishes treated 1, 2, 4 and 6 days before and maintained inside during 20 minutes. The results showed that methyl-parathion 0.4% commercial product killed all weevils, having a maximum residual effect of 6 days. Dicrotophos and ethyl-parathion 0.4% commercial

Citations: 24) Sensei, N; Toxic Organic Chemicals in Porous Media (Ecological Studies 73) 1989, 37 The stability of 9 organophosphorus insecticides (azinphos-Et, azinphos-Me, diazinon, EPN, ethion, fonofos, malathion, phosmet, parathion-methyl) was evaluated under a variety of storage conditions. Large vols. of surface water (4 l) were extd. using large particle-size graphitized carbon black cartridges (Carbopack B 60-80 mesh). The effect of temp., matrix type, and cartridge drying on recovery of these pollutants, after different storage periods, was studied and compared to the conservation of surface water in bottles. After a 2-mo period, all chems. stored on cartridges and kept at -20 Deg remained stable, with recoveries of 70-134%. By contrast, phosmet and EPN could no longer be recovered from the bottled surface water. Cartridges kept at -20 Deg fared better than did those stored at 4 Deg and 20 Deg. The type of matrix water selected

appears to have kept the target pesticides stored on cartridges from degrading, compared to Milli-Q water, in which malathion and phosmet were unstable. The effect of cartridges being either wet or dry made no difference in terms of improving pesticide recovery. After immediate surface water extn., the most practical storage condition for the target insecticides was storage on cartridges in the dark at -20 Deg, with no drying or solvent washing of the Carbopack B material. 1102. Sack, John S., Saper, Mark A., and Quiocho, Florante A. (1989). Periplasmic binding protein structure and function : Refined X-ray structures of the leucine/isoleucine/valine-binding protein and its complex with leucine. *Journal of Molecular Biology* 206: 171-191.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

The three-dimensional structure of the native unliganded form of the Leu/Ile/Val-binding protein (Mr = 36,700), an essential component of the high-affinity active transport system for the branched aliphatic amino acids in Escherichia coli, has been determined and further refined to a crystallographic R-factor of 0[middle dot]17 at 2[middle dot]4 A resolution. The entire structure consists of 2710 non-hydrogen atoms from the complete sequence of 344 residues and 121 ordered water molecules. Bond lengths and angle distances in the refined model have root-mean-square deviations from ideal values of 0[middle dot]05 A and 0[middle dot]10 A, respectively. The overall shape of the protein is a prolate ellipsoid with dimensions of 35 A x 40 A x 70 A. The protein consists of two distinct globular domains linked by three short peptide segments which, though widely separated in the sequence, are proximal in the tertiary structure and form the base of the deep cleft between the two domains. Although each domain is built from polypeptide segments located in both the amino (N) and the carboxy (C) terminal halves, both domains exhibit very similar supersecondary structures, consisting of a central [beta]-sheet of seven strands flanked on either side by two or three helices. The two domains are far apart from each other, leaving the cleft wide open by about 18 A. The cleft has a depth of about 15 A and a base of about 14 A x 16 A. Refining independently the structure of native Leu/Ile/Val-binding protein crystals soaked in a solution containing -leucine at 2.8 A resolution (R-factor = 0.15), we have been able to locate and characterize an initial, major portion of the substrate-binding site of the Leu/Ile/Val-binding protein. The binding of the -leucine substrate does not alter the native crystal structure, and the -leucine is lodged in a crevice on the wall of the N-domain, which is in the inter-domain cleft. The -leucine is held in place primarily by hydrogen-bonding of its [alpha]-ammonium and [alpha]-carboxylate groups with main-chain peptide units and hydroxyl side-chain groups; there are no salt-linkages. The charges on the leucine zwitterion are stabilized by hydrogen-bond dipoles. The side-chain of the -leucine substrate lies in a depression lined with non-polar residues, including Leu77, which confers specificity to the site by stacking with the side-chain of the leucine substrate. So far in our high-resolution crystallographic studies of several binding proteins (including those with specificities for -arabinose, -galactose, and sulfate), we have observed three structural forms that are related by flexible domains: an unliganded form with a wide open substrate-binding site cleft between the two domains, an "open" structure with the substrate bound to one domain, and a "closed" form with the substrate bound in the cleft and completely entrapped between the domains. The function of binding proteins in active transport is discussed in light of the existence of the various forms and the other common structural and ligand-binding features of these proteins. http://www.sciencedirect.com/science/article/B6WK7-4DN8X5H-PS/2/5918ceae42413249edb3c92becb11615

1103. Sagik, B. P., Sorber, C. A., Funderburg, S. W., and Moore, B. E. (Assessment of the Potential Health Risks Associated With the Injection of Residual Domestic Wastewater Sludges Into Soils. Final Report Ii. Laboratory Studies. *Govt reports announcements & index (gra&i), issue 15, 1980*.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE, VIRUS.

ABSTRACT: TD3: Movement of poliovirus 1, reovirus 3, and bacteriophage 0X174 was studied in nine different soils and two soils amended with sludge. Soils were sampled to a depth of 100 cm in three 33 cm profiles. These profiles were packed into acrylic cylinders, 10 cm in diameter and 33, 66, and 100 cm in length, according to the vertical distribution and bulk density of the soil as found in the field. Viruses were added to the columns in 100 ml of autoclaved secondarily treated wastewater. Columns then were flooded with 800 ml of autoclaved wastewater followed by 800 ml of distilled water for five cycles of wastewater/distilled water application. Column percolates were monitored for viral infectivity, specific conductance, pH, turbidity, and total organic carbon. Cation exchange capacity, percent organic carbon, pH, percent silt/clay, and specific surface area were determined for each soil studied. Recovery of all three virus types in soil column percolates followed a cyclical pattern with a peak of viral re

1104. Sagun, V. G. and Van Der Ham RWJM (2003). Pollen Morphology of the Flueggeinae (Euphorbiaceae, Phyllanthoideae). *GRANA, 42 (4) pp. 193-219, 2003*.
Chem Codes: Chemical of Concern: PSM Rejection Code: SURVEY.

ISSN: 0017-3134
Abstract: A total of 129 species from the subtribe Flueggeinae of the tribe Phyllantheae (Euphorbiaceae, Phyllanthoideae) were investigated using light and scanning electron microscopy, and 10 species using transmission electron microscopy, in order to evaluate the relationships between the eight constituent genera: Breynia, Flueggea, Glochidion, Margaritaria, Phyllanthus, Reverchonia, Richeriella, and Sauropus. Of these genera, Flueggea, Margaritaria and Richeriella share pollen with a prolate spheroidal meridional outline and a 3-colporate aperture system. Pollen of Reverchonia is also 3-colporate, but differs from that of the Flueggea alliance by its clearly prolate shape, tilioid ornamentation and absence of costae endopori. Breynia and Sauropus have 4-12 and 3-16-colporate pollen, respectively, with diploporate colpi. Two pollen types are recognised in Breynia, and four in Sauropus, one of which supports the recognition of Sect. Hemisauropus. Glochidion pollen is 3-6-colporate, and similar to that of Breynia in having reticulate sculpture with Y-shaped sexine structures, but it has monoporate colpi. Of the genus Phyllanthus, only species with pollen with diploporate colpi have been studied. Seven types are described. Diploporate Phyllanthus pollen can be distinguished from that of Breynia and Sauropus by its distinct colpus margins consisting of parallel muri. Colpal irregularities and endoaperture configurations in the subtribe are discussed, and pollen morphological trends are hypothesised. Placed in the successiform aperture series, the Flueggea alliance and Reverchonia form a basal group. Glochidion is considered intermediate, giving rise to the Breynia-Sauropus group. The

relationship with Phyllanthus remains unclear.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. We studied multi residue method of pesticides using Luke Method extraction, gel permeation chromatography (GPC) and dual column GC. A sample was extracted with acetone and filtered. Aliquot of the extracts was extracted with dichloromethane-petroleum ether (1:1) without evaporation of acetone. The extract was dehydrated, evaporated in vacuo, dissolved in dichloromethane-cyclohexane (1:1) and cleaned up by GPC using Bio Beads S-X3 and mobile phase dichloromethane-cyclohexane (l:l). The eluate fraction of pesticides was evaporated in vacuo and dissolved in acetone. The sample was determined with a dual column GC (column DB-1 and DB-1701, or DB-210 and DB-1) equipped with NPD and FPD. Silica gel column fractionation was effective for furthermore clean-up. Recoveries of 65 organic phosphate, carbamate and nitrogen containing pesticides from fortified tomato, lettuce and strawberry ranged 53-122%, except propamocarb, acephate, methamidophos and aldicarb. This multi residue m

A good linear correlation between log BCF and ei and eo was established over the 107 chems. by a multiple regression: log BCF = -0.00458.ei + 0.00991.eo (n = 107, r2 = 0.936, s = 0.735). The results suggest that ei and eo can be a good predictor of bioconcn. of org. chems. in fish and broaden its applicability in this particular field. Citations: 29) Ministry of Health and Welfare; Notification No 95 of Environmental Health Bureau 1996 A method is described for the rapid detn. of pesticide residues in agricultural products. Pesticides were extd. from samples with acetonitrile. To remove pigments and fatty acids, an aliquot of the ext. was cleaned up by a mini-column that was packed both with graphitized carbon black and primary secondary amine. Anal. was performed by gas chromatog./mass spectrometry with programmable temp. vaporizer-based large vol. injection using a liner packed with phenylmethylsilicone chem. bonded silica. The method was evaluated for 114 pesticides by spiking into tomato, spinach, Japanese pear, grape, and brown rice at various concns. of each pesticide (0.02-0.4 mg/g). The method, which gave good recovery (>60%) for 108 pesticides, is characterized by high cleanup efficiency and short cleanup time, and is useful as a rapid screening anal. Citations: Zar, J; Biostatistical Analysis 1998 The acute toxicity of 468 org. pollutants to planktonic crustaceans (Branchiopoda, Copepoda and Ostracoda) from pre-existing data was compared by means of statistical anal. and relative tolerance indexes (Trel). A surrogate species commonly used in toxicity bioassays (Daphnia magna) showed toxicity levels - within one order of magnitude - similar to all other Cladocera species, at least for 82% of the chems. studied. All neurotoxic insecticides except neonicotinoids, PCBs, organometallic compds. and PAHs are the most toxic substances to these organisms. Sensitivity levels among taxa were compared for individual chems. as well as groups of chems. with similar characteristics. While there are marked differences in sensitivity among taxa and particular groups of chems., no consistent trends were found for freshwater and saltwater species in relation to the latter groups. No correlation between LC50 and size of these organisms was found other than by chance, making extrapolations based on allometric equations impossible. A ref. guide for the effects of chems. on crustaceans. [on SciFinder (R)] 0269-7491 toxicity/ org/ pollutant/ planktonic/ crustacea/ Branchiopoda/ Copepoda/ Ostracoda

Many of the organophosphorus pesticides studied are absorbed into the interlayer space of montmorillonite. The intercalation causes different degrees of expansion (different types of complexes) principally as a function of the chem. structure of the org. compd. The presence in the org. mols. of the P:O and P:S groups and the size and compn. (functional groups present) of the radicals are the 2 most important factors. Both the nature of interlayer cations and the previous hydration status of montmorillonite influence adsorption. In some cases the polarizing power of the interlayer cation is a conditioning factor of the degree of interlayer expansion, whereas in others the cation charge is responsible for this. Results of IR spectroscopy show that interaction is of the dipole ion type and that it depends on the presence of the P:O or P:S group in the mol. and also on the functional groups present in the side chains. These factors, together with the situation of these latter groups in the side chains, condition the arrangement adopted by the mols. of a pesticide in the interlayer space. CAS Registry Numbers: 732-11-6 Role: BIOL (Biological study) (montmorillonite interaction with); 1318-93-0 Role: BIOL (Biological study) (phosmet interaction with) Phosmet (I) [732-11-6] interaction mechanism with montmorillonite [1318-93-0] was studied in an org. medium, using x-ray diffraction and IR spectroscopy. I forms definite and stable interlayer complexes with montmorillonite of 16.05-angstrom basal spacing. The expansion is not affected by the hydration status of the clay, the time of contact, or the concn. of the I soln. (>=5%). The nature of the interlayer cations affects the expansion. The shifts of the P:S and C:O stretching frequencies in the IR spectra, as a function of the interlayer cation and hydration status of the complexes, indicate that I mols. interact with the interlayer cations through both the O of the C:O group and the S of the P:S group. In the latter case, this interaction occurs directly or indirectly, according to the hydration status of the complex. According to these results and the dimensions of the I mol., the complex is a monolayer. The possible orientation of the org. mols. within the interlayer space is suggested. CAS Registry Numbers: 67034-67-7; 68136-58-3; 69402-28-4 Role: CAT (Catalyst use), USES (Uses) (catalysts, for hydrolysis of phosmet); 732-11-6 Role: RCT (Reactant), RACT (Reactant or reagent) (hydrolysis of, montmorillonite-catalyzed); 1318-93-0; 7447-39-4; 7786-30-3; 10043-52-4; 10361-37-2; 12173-47-6; 12174-06-0 Role: RCT (Reactant), RACT (Reactant or reagent) (phosmet hydrolysis catalyzed by) Factors that influence the catalytic hydrolysis of phosmet (I) [732-11-6] by montmorillonite [1318-93-0] and also the hydrolysis mechanism were studied. The catalytic activity of montmorillonite depends on the nature of the interlayer exchange cation and on the total or tetrahedral layer charge of the silicate; both factors condition the accessibility of the org. mol. to the exchangeable cation for the formation of interlayer complexes. The half-life of I in an aq. soln. at pH 6 is 500-fold greater in the system free of clay than in the presence of Ca-montmorillonite. The catalytic activity of the cations as montmorillonite exchangeable cations and as salts was compared. The process of hydrolysis in the presence of montmorillonite occurs in 2 stages, both of 1st-order kinetics, with different hydrolysis rates, the 1st stage having a high hydrolysis rate of short duration, and the 2nd having a slow and continuous one. The bidentate complex formed by I and the interlayer exchangeable cations, discussed in an earlier publication, must be the cause of hydrolysis. This interaction must enhance the electrophilic nature of the P atom, thus facilitating its nucleophilic attack by the OH- ion, producing P-S bond fission. Citations: 6) Sandra, P; J Chromatogr A 2003, 1000, 299 The performance of stir bar sorptive extn. (SBSE) for enrichment of pesticides from different matrixes is discussed. Emphasis is on vegetables, fruits and baby food because this is much more challenging than enrichment from aq. samples. By applying a new thermal desorption unit (TDU) fully automated and unattended desorption of 98 stir bars is feasible, making SBSE very cost-effective. The presence of pesticide residues is elucidated with the retention time locked gas chromatog.-mass spectroscopy method (RTL-capillary GC-MS). With SBSE-RTL-CGC-MS operated in the scan mode, more than 300 pesticides can be monitored in vegetables, fruits and baby food and 400 in aq. samples such as water or beverages. The multi-residue method (MRM) described provides detectabilities complying with the max. residue levels (MRL) set by regulatory organizations for pesticides in different matrixes. Chem Codes: Chemical of Concern: PSM Rejection Code: HUMAN HEALTH.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Of the 88 cases admitted to Hacettepe University Children's Hospital between 1973 and 1988, 86.2% had high toxicity from organophosphorous compounds having a low LD50 value. Only 13.6% of the patients were intoxicated by low toxic organophosphorus compounds. It is emphasized that all organophosphorus compounds apart from their toxic grade and LD50 value can cause intoxication.

Descriptors: Taxonomic significance
Abstract: Pollen morphology of ten Enkianthus species was examined using light (LM) and scanning electron microscopy (SEM) and previous infrageneric classification of Enkianthus was discussed in the light of the palynological characters obtained in this study. The pollen grains are monads, oblate spheroidal to prolate in shape and 3- to 5-colpor(oid)ate. Exine sculpture varies from granulate to coarsely rugulate-psilate with faint to distinct minute granules in SEM. Infraspecific geographical differences in palynological characters were found in E. deflexus. The species of Enkianthus are clearly differentiated into two pollen morphological groups that correspond to the sections Enkiantella + Meisteria and Andromedina + Enkianthus, respectively. The members of the sections Enkiantella and Meisteria have pollen grains typically with three apertures, prolate spheroidal to prolate, ratio of colpus length to polar axis (L/P) 0.69-0.84, relatively thinner exine and exine sculpturing tendency to granulate, character states that are probably plesiomorphic in this genus. The members of the sections Andromedina and Enkianthus have more derived pollen grains with four to five apertures, commonly oblate spheroidal, L/P 0.56-0.63, relatively thicker exine and exine sculpturing tendency to coarsely rugulate-psilate. It seems to be difficult to differentiate between sections of the same group on the basis of palynological characters only. Adding the palynological characters to the infrageneric framework of Anderberg indicates an evolutionary trend in exine sculpture within Enkianthus from finely verrucate-rugulate through coarsely rugulate to coarsely rugulate-psilate. A dichotomous key for Enkianthus was prepared based on the palynological characters. (copyright) 2006 Taylor & Francis.

CAS Registry Numbers: 55-38-9 (Fenthion); 56-38-2 (Parathion); 60-51-5 (Dimethoate); 62-73-7 (Dichlorvos); 119-12-0 (Pyridaphenthion); 121-75-5 (Malathion); 122-14-5 (Fenitrothion); 298-04-4 (Disulfoton); 333-41-5 (Diazinon); 470-90-6 (Chlorfenvinphos); 732-11-6 (Phosmet); 2104-64-5 (EPN); 2310-17-0 (Phosalone); 2597-03-7 (Phenthoate); 2636-26-2 (Cyanophos); 2921-88-2 (Chlorpyrifos); 3811-49-2 (Salithion); 5598-13-0 (Chlorpyrifos methyl); 13067-93-1 (Cyanofenphos); 17109-49-8 (Edifenphos); 21609-90-5 (Leptophos); 26087-47-8 (IBP); 34643-46-4 (Prothiophos) Role: ANT (Analyte), ANST (Analytical study) (detn. of, in food, by gas chromatog.) A simple and efficient cleanup method for gas chromatog. detn. of 23 organophosphorus pesticides in crops including onion is described. The sample was extd. with acetone. The ext. was purified with coagulating soln., which contained ammonium chloride and phosphoric acid, and then filtered by suction. The filtrate was dild. with NaCl soln. and reextd. with benzene. The org. layer was evapd. and injected into a gas chromatograph equipped with a flame photometric detector (FPD) and fused silica capillary columns (0.53 mm) coated with silicone equiv. to OV-1701, OV-1, and SE-52. Onion ext., which contained FPD interferences, was cleaned up on a disposable silica cartridge. Recoveries of most organophosphorus pesticides from spiked crops: mandarin orange, tomato, spinach, sweet pepper, broccoli, lettuce, and onion at levels of 0.02-0.28 ppm, exceeded 80%, but the water-sol. pesticides dichlorvos and dimethoate gave poor recoveries in all crops; the nonpolar pesticides disulfoton, chlorpyrifos, fenthion, prothiophos, and leptophos were not recovered quant. in spinach, sweet pepper, broccoli, and lettuce. IBP, edifenphos, phosmet, and pyridaphenthion were not recovered from onion because of adsorption to the silica cartridge. The detection limits ranged from 1.25 to 17.5 ppb on a crop basis. Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. An enzyme with high specific affinity for organophosphate and N-methylcarbamate insecticides has been incorporated into a new test for detection of these insecticides at the level of parts per billion (ppb) (commercially available as the Charm Pesticide Test). To measure the extent of insecticide inhibition of the enzyme, a specific bioluminescent substrate is used. The signal is counterproportional to the amount of insecticides. Random sampling of four baby food brands and testing for the cumulative levels of organophosphate and N-methylcarbamate insecticides found carbaryl to be the most common residue. Out of the 155 samples tested there were 132 negative samples (85.2%) and 23 suspected positive samples (14.2%). The suspected positive samples were further analyzed by high-performance liquid chromatography (RPLC) and gas chromatography/mass spectrometry (GC). Carbaryl was confirmed in 18 of the samples. One of the samples contained an active metabolite of tetrachlory

The median inhibitory concns. for these compds. ranged over several orders of magnitude. However, these values did not correlate with the literature reported in vivo rodent toxicities of the corresponding insecticides. Preincubation of an arbitrary selection of 18 of these insecticides with rat hepatic S-9 fractions altered their anticholinesterase activities so that they became predictive of their relative in vivo toxicities. This approach may be of utility in assessing the toxicity of these classes of compds. in vivo. [on SciFinder (R)] 0888-319X cholinesterase/ carbamate/ organophosphate/ insecticide/ neuron

1122. Sazonov, P. V. (Basic Directions in the Developmental Patterns of an Assortment of Organic Pesticides. *Zashch. Rast. (Moscow) 9: 20-21; 1974.*
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: PESTAB. The basic trends in the development of the assortment of pesticides in the USSR are outlined. The development of new preparations with reduced toxicity to warm-blooded animals has been the most characteristic trend during the last decade. Most modern pesticides have LD50 values ranging from 200 to 1,000 mg/kg, while the LD50 of tedion (tetradifon) and neoron (bromopropylate) is over 5,000 mg/kg. Along with the development of low-toxicity preparations, highly persistent pesticides, such as DDT, polychloropinene (strobane), and polychlorocamphene (toxaphene), will be phased out gradually. The combination of chemical and biological means of pest control is made possible by the development of preparations with very low toxicity in entomophagous species as compared with their toxicity for the pests to be controlled, e.g., rogor

(dimethoate), phosalone, menazon, and phthalophos (phosmet). Pest control with preparations pertaining to different classes is expected to prevent the manifestation or reduce the resistance of pests to pesticides.

Chem Codes: Chemical of Concern: PSM Rejection Code: NO TOXICANT.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Burning alfalfa (Medicago sativa (L.)) stubble in the spring has been shown to be effective in reducing some insect pest populations. A study was conducted to determine the long-term effect of this practice on seed yield. Plots were established at Lethbridge, Alberta, and burned in the spring or fall at various heights of plant growth from 1983 to 1989, with one half of each plot treated annually with insecticides when the pest insects were in their most vulnerable stage. Yields from burned treatments were not significantly different from unburned ones for the years 1983 to 1986, and 1988. In 1987, treatments burned in the fall had significantly higher yields than other treatments. Burning at 15-20 cm of growth significantly reduced yield compared to burning before spring growth. In 1989, yields from plots burned at 15-20 cm of growth were significantly lower than those burned every fall or spring. Insecticide treated plots had significantly higher yields in all years e

1127. Schamberger, M. R., Peters, J. E., and Leong, K. H. (1990). Collection of prolate spheroidal aerosol particles by charged spherical collectors. *Journal of Aerosol Science* 21: 539-554.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The effects of electrostatic forces and torques on the dynamics of prolate spheroidal particles are examined in relation to collision with a 30 [mu]m radius collector droplet. When the non-spherical particles are uncharged the influence of the electrostatic torque can lead to either increases or decreases in collision efficiencies. Initial particle orientation is shown to be important for low collector charges but insignificant for high collector charges, when the electrostatic torque aligns the particle parallel to the electric field. For the charged particle case, where the Coulombic force is dominant, the collision efficiencies for particles having large aspect ratios are significantly lower than those for spherical particles. Depending on the particle and collector charge levels, both front and back capture modes are found. Image forces are shown to be insignificant for highly charged particles. http://www.sciencedirect.com/science/article/B6V6B-488G51G-11/2/d45aaa8ceddd9e2487d284dca2fa726f

Chem Codes: Chemical of Concern: PSM Rejection Code: NO SPECIES (DEAD).

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. A pesticide residue screening program for 111 pesticides was performed on 6970 produce samples. Of the 81 varieties of samples, 2.4% contained illegal levels of pesticide residues (that is, higher than U.S. Environmental Protection Agency (EPA) tolerance or no tolerance specified), and 13.3% contained levels within tolerable limits established by EPA. Pesticide results are presented both by commodity and category type. The nature of violative residues is discussed.

1129. Schaub, S. A., Bausum, H. T., and Taylor, G. W. (Fate of Virus in Wastewater Applied to Slow-Infiltration Land Treatment Systems. *Appl environ microbiol. 1982, aug; 44(2):383-94. [Applied and environmental microbiology]: Appl Environ Microbiol*.
Chem Codes: Chemical of Concern: PSM Rejection Code: VIRUS.

ABSTRACT: The removal of seeded coliphage f2 and indigenous enteroviruses from primary and secondary wastewaters applied by spray irrigation to sandy loam and silt loam soils in field test cells was examined. The amount of f2 recovered from 170-cm-deep soil percolate samples taken over a 53-day period never exceeded 0.1% of applied virus levels and was usually below detection limits. Indigenous enterovirus levels in percolate waters also constituted only a small portion of those found in the wastewaters. At 10 days after seeding, f2 virus was present throughout the soil column but tended to accumulate around the soil core middepths. Coliphage f2 disappeared from the soil surface regions at a high rate, and by 53 days very little virus could be detected within the

length of the soil columns. Sterilized soil core segments from different depths were studied to determine their virus adsorption capabilities when suspended in either wastewater, test cell percolate water, or distilled water containing divalent cations. The adsorptive capacity of Windsor and Charlton soils for poliovirus 1 and coliphage f2 increased greatly with the soil sample depth until leveling off at the midcore depths. Soil suspended in wastewater had the least virus adsorption capability for all depths studied.

Sample exts. of apples, peas, green beans, oranges, raspberries, clementines, carrots, and wheat obtained using the Food and Drug Administration (acetone extn.) and Canadian Pest Management Regulatory Agency (acetonitrile extn.) multiresidue methods for pesticides were subjected to clean-up using different solid-phase extn. (SPE) cartridges in an attempt to reduce or eliminate the matrix enhancement effect. The matrix enhancement effect is related to the blocking of active sites on the injector liner by matrix components, thereby increasing signal in the presence of matrix vs. stds. in solvent in which the pesticides themselves interact with the active sites. Graphitized carbon black (GCB) was often used in combination with various anion-exchange SPE cartridges. The exts. were then spiked with organophosphorus insecticides. These process stds. were then compared to stds. in acetone of the same concn. using gas chromatog. with flame photometric detection or ion trap mass spectrometric detection. Sample matrix enhancement varied from little to no effect for some pesticides (e.g. chlorpyrifos, malathion) to >200% in the case of certain susceptible pesticides. The GCB removed color components but showed little effect in reducing matrix enhancement by itself. The anion-exchange cartridges in combination with GCB or not, substantially reduced the matrix enhancement effect but did not eliminate it. (SPME) was developed for the anal. of 20 pesticides commonly used in the Alsace region in rainwater samples. Since the pesticides were expected to be present at very low concns. and in complex matrixes, the anal. method used was both highly selective and sensitive. Therefore, fibers coated with polyacrylate (PA), polydimethylsiloxane (PDMS) and polydimethylsiloxane-divinylbenzene (PDMS-DVB) were tested, and the parameters affecting the precision and accuracy of the SPME method were studied and optimized. These parameters include the type of fiber, the adsorption time, the effect of salt, and the extn. temp. The PDMS fiber was the most polyvalent for the extns. of the different pesticides studied. Detection limits of between 5 and 500 ng L-1, depending on the compds. under study (except for those which could not be analyzed: captan and mevinphos), were obtained with this anal. procedure. This method was applied to the anal. of rainwater samples collected simultaneously on a weekly basis at one rural and one urban site between Mar. 2002 and July 2003. While some of the 20 pesticides analyzed were constantly detected (such as lindane and atrazine), a strong temporal variability was obsd. for some of the others (including alachlor, metolachlor, atrazine). Citations: 35) Bidleman, T; Environ Sci Technol 1988, 22, 361 A multiresidue method using gas chromatog. coupled to ion-trap tandem mass spectrometry (MS/MS) was developed for the anal. of 27 pesticides, commonly used in Alsace, in atm. samples (particle and gas phases). As pesticides are expected to be present at very low concns. and in a complex matrix, the anal.

method used was both highly selective and sensitive. These two properties were obtained by assocg. chromatog. with ion-trap MS/MS. To develop this method, anal. of electron impact in single MS was 1st conducted to choose the parent ions of the pesticides studied. Among the 27 pesticides analyzed, seven of them require a derivatization step. This was the case of some ureas (chlorotoluron, diuron and isoproturon), phenoxy acids (2,4-dichlorophenoxyacetic acid, 4-chloro-2-methylphenoxyacetic acid and mecoprop) and of bromoxynil. The derivatization was performed with success with pentafluorobenzylbromide. Then, a MS/MS method was optimized by parameters such as the radio frequency storage level and the collision-induced dissocn. excitation voltage. Finally, a last step enabled the development of two calibrating programs based on the quantification of daughter ions for the 20 pesticides analyzed directly (run 1) and for the seven pesticides which needed derivatization (run 2). With this anal. procedure, the detection limits varied between 2.5 and 1,250 pg m-3 depending on the compds. studied. This method was tested with success for atm. samples collected in Strasbourg (France) during intensive pesticide treatment in 2002. 1138. Scheyer, Anne, Morville, Stephane, Mirabel, Philippe, and Millet, Maurice (Pesticides analysed in rainwater in Alsace region (Eastern France): Comparison between urban and rural sites. *Atmospheric Environment* In Press, Corrected Proof: 1019.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

Current-used pesticides commonly applied in Alsace region (Eastern France) on diverse crops (maize, vineyard, vegetables, etc.) were analysed, together with Lindane, in rainwater between January 2002 and June 2003 simultaneously on two sites situated in a typical rural (Erstein, France) and urban area (Strasbourg, France). Rainwater samples were collected on a weekly basis by using two automatic wet only collectors associated with an open collector for the measurement of rainwater height. Pesticides were analysed by GC-MSMS and extracted from rainwater by SPME. Two runs were performed. The first one was performed by using a PDMS (100 [mu]m) fibre for pesticides where direct injection into GC is possible (alachlor, atrazine, azinphos-ethyl, azinphos-methyl, captan, chlorfenvinphos, dichlorvos, diflufenican, [alpha]- and [beta]-endosulfan, iprodione, lindane, metolachlor, mevinphos, parathion-methyl, phosalone, phosmet, tebuconazole, triadimefon and trifluralin). The second run was performed by using PDMS/DVB fibre and this run concerns pesticides where a preliminary derivatisation step with pentafluorobenzylbromide (PFBBr) is required for very low volatiles (bromoxynil,2,4-MCPA, MCPP and 2,4-D) or thermo labiles (chlorotoluron, diuron and isoproturon) pesticides. Results showed that the more concentrated pesticides detected were those used as herbicides in large quantities in Alsace region for maize crops (alachlor, metolachlor and atrazine). Maximum concentrations for these herbicides have been measured during intensive applications periods on maize crops following by rapid decrease immediately after use. For Alachlor, most important peaks have been observed between 21 and 28 April 2003 (3327 ng L-1 at Erstein and 5590 ng L-1 at Strasbourg). This is also the case for Metolachlor where most important peak was observed during the same week. Concentrations of pesticides measured out of application periods were very low for many pesticides and some others where never detected during this period. This is the case for diflufenican which was detected only during application. Two important peaks of concentrations were observed; a first one (101 ng L-1) in Erstein in November 2002 (4-11 November) and a second one (762 ng L-1) also in Erstein (28 April-15 May). The same behaviour can be seen for chlorfenvinphos and phosalone which have been detected, respectively, 2 and 4 times in Erstein and Strasbourg at high concentrations (28 April 2003-15 May 2003, 187 ng L-1 of phosalone and 157 ng L-1 of chlorfenvinphos in Erstein). MCPP, 2,4 MCPA and 2,4-D have been detected at high concentrations in rainwater but for the other pesticides very episodically and mainly during their use in agriculture. Maximal concentrations of MCPP and 2,4 MCPA have been measured in Erstein between 28 April and 15 May (904 and 746 ng L-1, respectively). Comparison between rural and urban sites showed that concentrations in rural areas are generally higher except for pesticides commonly applied in urban areas like Diuron. No seasonal phenomenon was observed for Diuron. This herbicide has been detected in practically all of the rainwater samples in Strasbourg (40/41) with a maximum of 1025 ng L-1 (16-23 September 2002) in 38 samples on 41 in Erstein with a maximum of 317 ng L-1 (15-23 October 2002). The total concentration of Diuron measured between 4 March 2002 and 20 July 2003 is of 4721 ng L-1 in Strasbourg and 5025 ng L-1 in Erstein. This result shows that wet deposition of Diuron in urban and rural sites was equivalent and can be explained by the "urban use" of this molecule together with its potential persistence. Abstract: There are few consistent and comprehensive data sets for the calibration and verification of computer models of pesticide fate in agro-ecosystems. To partly close this gap the data base of the multidisciplinary Weiherbach research project was used to form a data set that is well suited for that purpose. It has been successfully used during the COST Action 66 model comparison. The Weiherbach research area is a small, intensively cultivated catchment in south-western Germany. The soils of the region are developed from loess and are strongly influenced by erosion. An important feature is the abundance of large macropores that cause preferential flow events. Field dissipation and field lysimeter studies with the herbicide isoproturon and the tracer KBr were conducted in a typical Calcaric Regosol for a late autumn as well as for a spring application scenario. For the lysimeter studies 10 undisturbed soil monoliths (0.45 m long, 0.3 m in diameter) from the same field were used to allow for an estimate of the spatial variability of solute transport. During the spring experiment, one half of the field plot and selected lysimeters were irrigated to simulate wet conditions with higher leaching potential. The Weiherbach data set comprehensively characterises the hydrological, agricultural and soil properties of the experimental sites (including site-specific degradation and sorption data for isoproturon) as well as the meteorological conditions during the experiments. In the field studies, depth profiles of isoproturon and tracer were measured at several dates whereas in the lysimeter studies the percolate was regularly analysed. A detailed description of the experimental results and the whole data set as it was used for the comparison of pesticide transport models within COST Action 66 will be given by Schierholz (1999). In the experiments both matrix and macropore flow occurred and the kind and amount of solute transport clearly depended on the precipitation (irrigation) conditions. The autumn application was followed by an unusually wet winter and represents a 'worst case' scenario with deep leaching of isoproturon. After the spring application there were about average meteorological conditions, but the irrigated variants again represent a 'worst case'. (C) 2000 Elsevier Science B.V.

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: TD3: Dissolved organic carbon (DOC) is important in the acid-base chemistry of acid-sensitive freshwater systems; in the complexation, mobility, persistence, and toxicity of metals and other pollutants; and in lake carbon metabolism. Carbon isotopes are used to study the origin, transport, and fate of DOC in a softwater catchment in central Ontario. Precipitation, soil percolates, groundwaters, stream, beaver pond, lake waters, and lake sediment pore water were characterized chemically and isotopically. In addition to total DOC, isotopic measurements were made on the humic and fulvic DOC fractions. In Water Resources Research: Vol. 20, no. 12, 1990.

The authors developed a safety-based strategy specifically aimed at setting limits for pesticide residues in baby foods. The approach is based on the acceptable daily intake (ADI) together with the application, when necessary, of an addnl. uncertainty factor to account for the potential higher sensitivity of infants to toxicants. The need for this extra factor is dependent on the toxicol. information available and may be particularly important for pesticides with a neurotoxic potential. Using this strategy the authors evaluated safety-based residue limits for finished products based on a std. food intake pattern of a 4-mo-old

infant. For most of the pesticides examd. the estd. limits fell within a range which can be controlled through existing quality assurance systems. This scientific approach appears usable in practice and is intended as a basis for stimulating discussions aimed at evaluating the need for new limits to ensure the optimal quality of infant products with respect to pesticide safety. This assessment demonstrates that for a no. of pesticides there is a need for adequate developmental studies to provide assurance that the current ADI is appropriate for infants. A consequence may be the necessity for enhanced anal. sensitivity for the detn. of pesticide residues in infant foods which would be compatible with limits based on an infant-adjusted ADI. ABSTRACT: TD3: Rain water, soil percolate (different depths) and ground water were sampled at 11 measuring stations and analyzed for organic compounds. In rain water trichloroacetic acid (TCA), 3-methyl-4-nitrophenol (3-M-4-NP) and 4-nitrophenol are the highest concentrated substances. Concentrations reach up to 3 nmol/l in open land, up to 5 nmol/l in beech woods and up to 10 nmol/l in spruce forestes. In the soil degradation processes occur. TCA is dehalogenated to dichloro- (DCA) and monochloroacetic acid (MCA) and decarboxylized to trichloromethane, respectively. 4-NP and 3-M-4-NP are mainly transformed to 2-nitrophenol (2-NP) and 4-methyl-2-nitrophenol (4-M-2-NP). These processes could be verified with a solid column experiment. The effects of these processes vary extremly from station to station. In ground water particularly the pedospheric degradation products occur (trichlorethan, 2-NP, MCA and DCA). Concentrations reach up to some nmol/l. (orig.). (Copyright (c) 1997 by FIZ. ABSTRACT: TD3: Large amounts of organic substances are emitted into the atmosphere as a consequence of human activity. The primary emissions as well as their atmospheric reaction products reach the soil via precipitation and may endanger ground-water quality. At four measuring stations in woodland areas of the Federal Republic of Germany which are not influenced by industry and agriculture, samples of rainwater, percolate from the upper soil layer and of the ground water (mainly spring water) were taken at monthly intervals over a period of one year both in the open land and in spruce forests. In addition to numerous single compounds from different substance classes (chlorinated hydrocarbons, aromatic substances, phthalates, chlorinated carbonic acids, nitrophenols), AOX (organic halogen compounds adsorbable to activated carbon) were determined as a characteristic organic group parameter of anthropogenic exposure. Of special importance concerning ground-water quality are chlorinated acetic acids as reaction pr

1145. Schmidt, Ulrike D. and Paradies, H. Hasko (1977). The structure of the [var epsilon]-subunit from the chloroplast coupling factor (CF1) studied by means of small angle X-ray scattering and inelastic light scattering. *Biochemical and Biophysical Research Communications* 78: 383-392.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The [var epsilon]-subunit from the chloroplast coupling factor (CF1) was purified on a BioGel A 0.5 m column, and the size, shape and radius of gyration were determined. The diffusion coefficient, D20, wo, was determined by means of inelastic light scattering and was found to be (11.3 +/- 0.05) x 10-7 cm2[middle dot]sec-1 and independent of pH and ionic strength. From the sedimentation coefficient (1.70S) and D20, wo we obtained a molecular weight of 11,900 with a partial specific volume of 0.740 +/- 0.003 ml [middle dot] g-1. The radius of gyration of [var epsilon] in 0.05 M TRIS-HCl, pH 7.0, was found to be 11.8 +/- 0.04 A, the volume 17.0 x 103 (A3) and the specific inner surface 0.19 A-1, indicating a spherical molecule with overall dimensions of D = 31.8 A with a given axial ratio of 1:1:2.4. The description of the [var epsilon]-subunit in solution as a prolate ellipsoid of revolution with half axes A = b = 12.7 A and C = 25.4 A was obtained from a comparison of the theoretical and the experimental scattering curves. The degree of hydration was determined to be 0.15 g H2O/g protein.

In this paper the results of three steps toward the evaluation of PEM are reported. The evaluation involves: (i) verifying the numerical algorithms and computer code through comparison of PEM simulations with an available anal. soln. of the advection/diffusion equation for semi-volatile solutes in soil; (ii) comparing hourly heat, moisture and emission fluxes of trifluralin and triallate modeled by PEM with fluxes measured using the relaxed eddy-accumulation technique; and (iii) comparison of the PEM predictions of persistence half-life for 29 pesticides with the ranges of persistence found in the literature. The overall conclusion from this limited evaluation study is that PEM is a useful model for estg. the volatilization rates of pesticides from agricultural soils and crops. The lack of reliable ests. of chem. and photochem. degrdn. rates of pesticide on foliage, however, introduces large uncertainties in the ests. from any model of the volatilization of pesticide that impacts the canopy. 1147. Schrumpf, Marion, Axmacher, Jan C., Zech, Wolfgang, Lehmann, Johannes, and Lyaruu, Herbert V. C. (2007). Long-term effects of rainforest disturbance on the nutrient composition of throughfall, organic layer percolate and soil solution at Mt. Kilimanjaro. *Science of The Total Environment* 376: 241-254.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

At the lower parts of the forest belt at Mt. Kilimanjaro, selective logging has led to a mosaic of mature forest, old secondary forests (~ 60 years), and old clearings (~ 10 years) covered by shrub vegetation. These variations in the vegetation are reflected by differences in nutrient leaching from the canopy and in both amount and quality of litter reaching the ground, thereby also influencing mineralization rates and the composition of seepage water in litter percolate and soil solution. The aim of this study was to investigate how above- and belowground nutrient dynamics vary between

regeneration stages, and if forest regeneration at the clearings is hampered by a deterioration of abiotic site conditions. K, Mg, Ca, Na and N compounds were analysed in rainfall, throughfall, organic layer percolate and the soil solution to a depth of 1.00 m at three clearings, three secondary forest and four mature forest sites. Element fluxes via throughfall showed only small variations among regeneration stages except for K and NO3-N. With 57-83 kg ha- 1 a- 1and 2.6-4.1 kg ha- 1 a- 1 respectively, K and NO3-N fluxes via throughfall were significantly higher at the clearings than at the mature forest sites (32-37 and 0.7-1.0 kg ha- 1 a- 1 for K and NO3-N). In organic layer percolate and in soil solution at 0.15-m soil depth, concentrations of K, Mg, Ca and N were highest at the clearings. In the organic layer percolate, median K concentrations were e.g. 7.4 mg l- 1 for the clearings but only 1.4 mg l- 1 for the mature forests, and for NO3-N, median concentrations were 3.1 mg l- 1 for the clearings but only 0.92 mg l- 1 for the mature forest sites. Still, differences in annual means between clearings and mature forests were not always significant due to a high variability within the clearings. With the exception of NO3-N, belowground nutrient concentrations in secondary forests ranged between concentrations in mature forests and clearings. Vegetation type-specific differences decreased with increasing soil depths in the soil solution. Overall, the opening of the forest led to a higher spatial and seasonal variation of nutrient concentrations in the seepage water. These results suggest differences in both mineralization rates and in nutrient budgeting at different regeneration stages. Since nutrient availability was highest at the clearings and no compaction of the soil was observed, deterioration of soil properties did not seem to be the main reason for the impeded regeneration on the clearings.

Their spectra show mol. ions of high abundance and characteristic fragmentation patterns. The phosphates and phosphorothionates usually show a-cleavage with respect to the P atom with and without proton transfer. In contrast, the phosphorothiolates and phosphorodithioates usually show b-cleavage from the P atom. Fragments with the charge retention on the P moiety were also obsd. in the field desorption mass spectra, although their abundances were low. Analyses of std. mixts. as well as some wastewater samples indicate that field-desorption mass spectrometry is suitable for the identification of organophosphorus pesticides at nanogram level in mixts. and environmental samples without preliminary sepn. and purifn. ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. To evaluate the effects of dry and wet deposition on forest trees (Picea abies (L.) Karst.), the LIS-Essen is operating an Open-Top Chamber Field Station within an area where novel forest decline has been prevalent since 1982. Chambers are ventilated with either ambient or charcoal-filtered air and receive either natural or artificial rain, the latter being prepared by natural rain and distilled water in ratio 1:10. Besides deposition data, acquired above and below the tree crowns as well as via lysimeters of soil percolates, various parameters describing vitality of trees are measured. To obtain a persuading representation of total parameters and their interdependencies, a multivariate graphical cluster analysis has been performed by use of Chernoff-Flury faces. Interdependencies of vitality parameters are more easily recognizable in this multivariate picture than in usually applies binary correlation diagrams.

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Mercury (Hg) and methylmercury (CH3Hg+) are global pollutants, but little information is available on their distribution and mobility in soils and catchments of Central Europe. The objective of this study was to investigate the pools and mobility of Hg and CH3Hg+ in different forest soils. Upland and wetland forest soils, soil solutions and runoff were sampled. In upland soils the highest contents of total-Hg were found in the Oh layer of the forest floor (> 400 ng g-1) and the storage of non geo tter layer of the forest floor and in the Bsv horizon. The CH3Hg+ content of the wetland soils was generally much higher in comparison with upland soils. CH3Hg+ in solution was found in the forest floor percolates of upland soils and in wetland soils, but not in soil solutions from mineral soil horizons. Gaseous losses of Hg as well as methylation of Hg are likely in wetland soils. The latter might be highly relevant for CH3Hg+ levels in runoff.

Abstract: Forested watersheds are an important part of the terrestrial mercury and methylmercury cycle, and a link between the atmospheric and aquatic environment. This study was conducted to determine the contribution of the forest floor to the pools and fluxes of total Hg (Hg sub(total)) and methylmercury (MeHg) in a forested catchment, and to identify factors influencing the mobility of both compounds. Throughfall deposition, litterfall, runoff and fluxes with forest floor percolate of Hg sub(total) and MeHg were sampled during one year in a coniferous catchment in Germany. Total deposition of Hg sub(total) was 552 mg ha sub(-1) a sub(-1) with litterfall contributing one third. Nearly 60% of the total input of Hg sub(total) reached the mineral soil with the forest floor percolate, but less than half of this fraction was found in the runoff of the catchment. Total deposition of MeHg was 2.6 mg ha sub(-1) a sub(-1), with litterfall as the dominating pathway. Only 19% of the MeHg deposition was discharged from the forest floor, but the flux of MeHg with runoff was nearly twice as high. Only few correlations with other solution parameters were found. Fluxes of both compounds with forest floor percolates depended mainly on water fluxes, which was not true for the runoff. The forest floor of the upland soil is an effective sink for MeHg, but not for Hg sub(total). Differences in the mobility of both compounds in the forest floor disappeared at the catchment scale, probably because other processes (i.e. Hg sub(total) immobilization and MeHg formation) dominated.

1153. Scott Angle, J. (1990). Nitrate leaching losses from soybeans (Glycine max L. Merr.). *Agriculture, Ecosystems & Environment* 31: 91-97.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

The leaching of nitrate-nitrogen (NO3---N) out of the root zone of soybeans (Glycine max L. Merr.) was monitored over a 3-year period. Soil percolate was collected montly and soil cores (2.1 m depth) were collected in the spring and fall of each year from plots cultivated using either conventional or no-till practices. Nitrate-N concentrations in percolate over the 3-year period averaged 13.7 and 14.4 mg l-1 from the conventional and no-till plots respectively. No significant tillage effect was noted. Highest percolate NO3---N concentrations were observed during the mid-winter months when rainfall was high and crop residues were being mineralized. In the fall of each year, highest soil NO3---N concentrations were found near the soil surface. In the spring, highest

soil NO3---N concentrations were usually found at a depth of 0.9-1.2 m, indicating that the mineralized N was leaching through the soil profile. These data suggest that only moderate quantities of NO3---N leach from the root zone of soybeans.

1155. Sedykh, A. S., Popov, P. V., Abelentseva, G. M., Shapovalova, G. K., and Ivanova, G. B. (Sensitivity of Biological and Thin-Layer Chromatographic Methods of Determining Pesticide Residues. *Probl. Anal. Khim.2: 130-135* 1972.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: PESTAB The biological method, using Calandra orysae, Drosophila melanogaster, and Culex pipiens molestus, was compared with thin-layer chromatographic methods for the determination of a variety of pesticide residues. The mosquito imago was most sensitive to the pesticides studied, permitting detection of quantities in the order of magnitude of 0. 00003 to 5 mg/l. The thin-layer chromatographic method, using a silica gel layer and bromophenol blue with silver nitrate and possibly acetic acid for visualization, was more than 100 times less sensitive than the gnat imago test for the detection of methyl ethyl parathion, fenitrothion, methyl parathion, malathion, phorate, trichlorfon, and dichlorvos, and 63, 19, 17, and 18 times less sensitive for phosmet, methylmercaptophos, phosalone, and carbaryl. The two methods were practically equivalent in the detection of vamidothion, dimethoate, and formothion. While the gnat imago test lacks specificity, it is more suitable for determination of the overall toxicity of the original active agent and its metabolites than the thin-layer chromatographic method. The biological method can be applied to the determination of pesticide residues in extracts from water, soil, plants, and animal tissues.

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The boundary element method (BEM) has been applied to the calculation of dielectric spectra of suspensions of rod-shaped cells using two kinds of models: model-R consisting of a cylinder and two hemispheres and model-PU of prolate spheroid shape. Both models have an insulating shell phase of a uniform thickness. The calculations were compared with those using a conventional

spheroidal model with a confocal shell (model-PC) and previous observations on rod-shaped yeast cells. The differences among the three models were not considerable and all the models succeeded in interpreting the observed data on yeast cells. Boundary element method/ Complex permittivity/ Dielectric relaxation/ Interfacial polarization/ Simulation

Chem Codes: Chemical of Concern: PSM Rejection Code: YEAST, MODELING.

In order to simulate dielectric relaxation spectra (DRS) of budding yeast cells (Saccharomyces cerevisiae) in suspension, the complex polarization factor (Clausius-Mossotti factor) [beta] for a single cell and the complex permittivity of a cell suspension [epsilon]sus* were calculated with a doublet-shaped model (model RD), in which two spheres were connected with a part of a ring torus, using the boundary element method. The [beta] values were represented by a diagonal tensor consisting of components [beta]z parallel to the rotation axis (z axis) and [beta]h in a plane (h plane) perpendicular to the axis. The [epsilon]sus* values were calculated from the complex permittivity of the suspending medium [epsilon]a* and the components of [beta]. The calculation was compared with that of a conventional prolate spheroid model (model CP). It was found that model CP could be used as a first approximation to model RD. However, differences existed in [beta]z between models RD and CP; [beta]z showed three relaxation terms in the case of model RD in contrast with two terms in model CP. Narrowing the junction between the two spheres in model RD markedly decreased the characteristic frequency of one of the relaxation terms in [beta]z. This suggests that the structure of the junction can be estimated from DRS. Effects of the shape change from model RD to a two-sphere model (model RD without the junction) were also examined. The behavior of [beta]z in the two-sphere model, the relaxation intensity of which was much lower than model RD, was quite similar to that in a single-sphere model. These simulations were consistent with the experimental observations of the dielectric behavior of the yeast cells during cell cycle progression. Abstract: This paper examines the problem of the nonreactive advective transport of a contaminant that is introduced at the boundary of a three-dimensional cavity contained in a fluid-saturated nondeformable porous medium of infinite extent. The advective Darcy flow is caused by a hydraulic potential maintained at a constant value at the boundary of the three-dimensional cavity. In order to develop a generalized solution to the problem the three-dimensional cavity region is modeled as having either a prolate or an oblate shape. Analytical results are developed for the time- and space-dependent distribution of contaminant concentration in the porous medium, which can also exhibit natural attenuation. The exact closed-form analytical results are also capable of providing solutions to advective transport problems related to spherical, flat disc-shaped and

elongated needle-shaped cavities.

Citations: 29) Grob, K; J High Res Chrom 1991, 14, 373 A method has been developed for the sample clean-up of organophosphorus pesticides (OPPs) in mussels prior to gas chromatog. anal. The system applied uses a HPLC pump and a silica gel column A diode array detector is used to monitor, on line, the elution of the fat present in the mussel soft tissue that was extd. with acetonitrile:acetone and redissolved in hexane. Polar and moderately polar pesticides were fractionated and sepd. from fats using hexane:ethyl acetate 95/5, vol./vol. as mobile phase. The most polar pesticides (chlorfenvinphos, phosmet, and dimethoate) were eluted from the column using Et acetate. For the elution of non polar pesticides (chlorpyrifos, phorate, and fonophos) in fat free fractions it was necessary to use hexane as mobile phase switching on to hexane:ethyl acetate 99/1 (vol./vol.) (4 mL) after 4 min of elution. Quant. measurement of fat content in collected fractions from LC system was carried out by colorimetry in order to know the efficiency of the clean-up and the amt. of fat injected in the GC system. Fat free fractions contg. pesticides obtained after LC clean-up can be injected directly, without further clean-up steps or solvent exchange, in the GC system. The limits of detection for the organophosphorus pesticides investigated varied between 1 and 40 ng/g using mass selective detector and between 0.1 and 2 ng/g using nitrogen-phosphorus selective detector. Recoveries of the overall procedure, including extn. and clean-up, were obtained at 400 and 40 ng/g levels and they varied between 89 +- 9% and 105 +- 4%. 1163. Seth-Paul, W. A. (1978). QQ and RQ--QP branch separations in type B band envelopes of asymmetric top molecules. *Journal of Molecular Structure* 50: 29-41.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Analysis of observed QQ and RQ--QP branch separations of type B band envelopes displayed by prolate and oblate asymmetric top molecules revealed that these separations can be estimated by means of the equation [Delta][nu](QQ) = S([varrho], [kappa])SB where SB is the calculated [3] PR-separation of the corresponding type B band. The separation function S ([varrho], [kappa]) is a product of two functions S([varrho],[kappa]) = [phi]([varrho])[phi]([varrho], [kappa]) one of which is a function of [varrho]. The second depends upon the shape of the molecule (prolate or oblate), [varrho] and [kappa] or merely [kappa] depending upon whether [varrho] is smaller or larger than . Agreement with observed separations is quite satisfactory for molecules with parameters 0 < [varrho] < 4 and -1 < [kappa] < + 1. The formulas are therefore proposed to substitute for the inter- and extrapolation technique usually applied to the theoretical curves of Badger and Zumwalt [1]. http://www.sciencedirect.com/science/article/B6TGS-44CYBXJ-CS/2/000ade56946d05bd80200e18e89f01b0

ABSTRACT: PESTAB. The effects of phosmet, prometryne, atrazine, desmetryne, and trichlorfon on the functional activity of bull heart submitochondrial particles were studied by spectrophotometric determination of the NAD-H oxidase activity. Increasing concentrations of the pesticides caused monotonical increasing inhibition of the NAD-H oxidase activity. The concentration dependence of the activity can be described by an exponential function. The pesticide concentrations causing 50% inhibition are 7.5 muM for phosmet, 145 muM for prometryne, 430 muM for atrazine, 700 muM for desmetryne, and 5,000 muM for trichlorfon. The findings indicate the possibility of using biological membranes as a model in studies on the biological activity of pesticides.

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Eight Dutch surface soils were used in this study to analyse different N fractions in 0.01 molL-1 CaCl2 extracts and percolates at different temperatures. The results obtained showed that: (1) The temperature of 0.01 molL-1 CaCl2 extracting and percolating solution had no influence on amount of NO3--N, the extractability of other N fractions (NH4+-N, total soluble N and reduced N), however, was evidently affected by the temperature in 0.01 molL-1 CaCl2 solutions. The hydrolysis of organic N was the predominant reason for this influence. (2) The release of organic soluble N obeyed the first order kinetics. A nonlinear least square method could best fit the experimental data into the model Nt = No(1--e-kt) with R- squared being higher than 0.99. (3) The kinetic values No were highly consistent with the soluble reduced N in extraction experiment. The 0.01 molL-1 CaCl2 solution extracted and released the labile organic N fraction. The determination of soluble organic N in 0.

The LD50 values ranged 2-7500 mg/kg. The half maximal effect (IC50) ranged from .apprx.10-6M for methylparathion [298-00-0], diazinon [333-41-5], paraoxon [311-45-5] and Vendex [13356-08-6] to >10-2M for chlorpyriphos [2921-88-2] and methylchlorpyriphos [5598-13-0]. Based on IC50 values, carbamate insecticides were less toxic than organophosphate insecticides. Some of these insecticides (such as leptophos [21609-90-5]) caused a slight stimulation of cellular growth at very low concns. At toxic concns., a dose-related but nonspecific inhibition of cell growth was found. The cytotoxic changes included decreased migration of cells from the culture implant, varicosities in and shortening of various cells, vacuolization and rounding of neuroglial cells, and pigmentary degeneration and complete abolition of the cell growth. No significant correlations of nerve fiber or glial cell cytotoxicity were apparent with other toxic or physicochem. properties such as LD in animals, cholinesterase inhibition, lipophilicity or water soly. of chems. Citations: Stan, H; J Chromatog 2000, 892, 347 The magnitude of contamination of pesticide residues including organochlorine, organophosphate, and carbamate was evaluated in animal feed conc. samples collected from Karnal (Haryana), India, in light of changed consumption pattern of pesticides in India. Out of 60 pesticides selected for multiresidue anal. only detected residues of phorate, monocrotophos, dimethoate, diazinon, carbaryl, chlorpyrifos, and p,p'-DDT were listed. Carbaryl was detected in 1 sample only. DDT was detected in 2 feed conc. samples. This decline in DDT levels could be attributed to the ban of DDT in the agriculture sector since 1984. Presence of organophosphate pesticide residues in animal feed samples is discussed to be due to major consumption of organophosphates in agriculture sector. [on SciFinder (R)] 0007-4861

Samples of infant milk food and weaning food collected from Karnal and Delhi, India, market monitored for 112 pesticides including organochlorines, organophosphates, organocarbamates and synthetic pyrethroids. The method includes extn. with acetonitrile and clean-up by acetonitrile-hexane partitioning and gel permeation chromatog. and estn. by GLC and GCMS. No pesticide residues were detected in any of the infant food and weaning food samples. The absence of pesticide residues in infant formulas might be attributed to the major presence of skim milk powder and exposure of 190 to 220 Deg temp. to infant formula ingredients (dry/wet blending) which might degrade the pesticide residues. Further, washing, blanching etc. of fruits and vegetables used as ingredients in weaning foods might result in degrdn. of residues. [on SciFinder (R)] 0019-5146 pesticides/ infant/ food/ milk

Abstract: It has been suggested that exposure of cattle to the ectoparasiticide Phosmet in the 1980s caused a conformational change in the cellular prion protein (PrP super(C)) to form the BSE prion (PrP super(SC)), which initiated the epidemic of bovine spongiform encephalopathy (BSE). Recombinant mouse cellular prion (r[mouse]PrP super(C)) was exposed to the organophosphorus pesticide Phosmet in vitro and the conformation of the prion before and after exposure was monitored using circular dichroism (CD) spectroscopy, utilizing synchrotron radiation at the Council for the Central Laboratory of the Research Councils (CLRC) facilities at Daresbury, UK. Metabolites of Phosmet, generated in situ by rat microsomes, were investigated in the same way, to determine whether they might initiate the conformational change due to their high chemical reactivity. Our studies showed that exposure of r[mouse]PrP super(C) to Phosmet or microsomes-generated metabolites of Phosmet did not result in the conformational change in the protein from alpha -helix to beta -pleated sheet that is characteristic of the PrP super(C) to PrP super(SC) conversion and, therefore, Phosmet is very unlikely to have initiated the BSE epidemic by a simple direct mechanism of conformational change in the prion protein.

(GC) with ion trap mass spectrometry (MS/MS) was developed. The sensitivity of this method for many analytes is or lower than those of selective GC detectors such as flame photometric detectors and electrolytic cond. detectors. Using MS/MS, very low detection limits and good confirmation (1 precursor ion and >=2 product ions) are achieved simultaneously. The entire list of pesticides is screened with 2 injections per sample. Samples are introduced onto the column by a temp.-programmed cold injection to maximize response. Each pesticide is run with its own unique set of parameters, which fragment the compd., retaining only the precursor ion. This ion is then refragmented to create a product spectrum. The selectivity of MS/MS gives a very clean spectrum, making compd. identification and confirmation clear, even with a relatively dirty food matrix. If care is taken to maintain the injection port and guard column, this method can reliably identify and confirm >100 pesticides at the low parts-per-billion range. Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. A simultaneous cleanup method for the determination of pesticide residues in agricultural products by GC and HPLC was developed. The elution patterns of 120 pesticides from a hard gel-type GPC column and an ENVI-Carb-NH2 mini-column were examined. Most of the pesticides were eluted in the 55 160 mL fraction from GPC with 30% acetone-cyclohexane (v/v) and in the 0 20 mL fraction from the mini-column with 25% toluene-acetonitrile (v/v). The results showed that these two cleanup methods were applicable for most of the pesticides. A sample was extracted with acetone and filtered. The extract was partitioned with saturated ammonium sulfate-ethyl acetate. The extract was dehydrated, evaporated in vacuo, dissolved in the GPC mobile phase and cleaned up by GPC. The eluate fraction of pesticides was evaporated in vacuo and dissolved in acetone. An aliquot of the acetone solution was cleaned up on a mini-column. The eluate was evaporated in vacuo and dissolved in acetone or aceto

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Pesticides and fertilizers are often broadcast on no-till fields in the spring when soil water content can be quite variable. Soil water content may influence the contribution of macropores and matrix porosity to water movement and chemical transport in subsequent rainfalls. Therefore, we surface-applied SrBr2-6H2), atrazine (2-chloro-4-ethylamino-6-isopropylamino-s-triazine), and alachlor (2-chloro-2',6'-diethyl-N-(methoxymethyl) acetanilide) on nine, 30 by 30 by 30 cm, undisturbed soil blocks obtained from a no-till corn (Zea mays L.) field and maintained at three initial moisture levels 1 h before a 30-mm, 0.5-h simulated rain. To distinguish applied water from resident water and assess interaction of the rainwater with the soil matrix, RbCl was added to the simulated rain as a tracer. Sequential percolate samples were collected from the base of the blocks in lysimeter. Flow-weighted concentrations of Cland Rb+, respectively, were 75 and 836% higher in percolate fro

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Decreased runoff from no-till fields combined with preservation of macroporosity increases the potential for transport of agricultural chemicals to groundwater. Our objective was to determine if macropores affect the movement of water and

surface-applied chemicals through the solum. Eight, 75-cm-long, 30-cm-diam. soil cores were obtained from a 17-yr-old, no-till, corn (Zea mays L.) field within a mapping unit a Rayne silt loam (fine-loamy, mixed, mesic Typic Hapludult). The cores were converted into column lysimeters and simulated tillage was performed on the upper 15 cm of four columns. The unvegetated columns were buried outside in a mowed area and received broadcast applications of NH4NO3 and SrBr2 6H2O each spring. During a 2-yr period, the no-till columns transmitted 36% more water than the tilled column. Yearly total amounts of Br- and NO3- in the percolate were unaffected by tillage, although the losses during the growing season were greater for the no-till colum

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Previous research has established that macropores can rapidly transmit water through soil. This observation has raised concern that macropores may also promote rapid movement of agricultural chemicals to groundwater. This is a particular concern for no-till fields where lack of disruption by tillage can lead to the devlopment of extensive macropore systems. In order to investigate the effect of initial rainfall on chemical transport, strontium bromide hexahydrate (SrBr2 6H2O) and atrazine (2-chloro-4-ethylamino-6-isopropylamino-s-triazine) were surface-applied to six 30 by 30 by 30 cm blocks of undisturbed soil obtained from a 25-yr-old, no-till corn (Zea mays L.) field with evidence of well-defined macropores attributable to earthworm activity. Half of the blocks then received a 1-h 5-mm

simulated rain, which did not produce percolate. Two days later, the blocks received a 0.5-h 30-mm simulated rain, followed by another 0.5-h 30-mm rain 1 wk later. The remaining blocks

1182. Shukla, G. , Kumar, A., Bhanti, M., Joseph, P. E., and Taneja, A. (Organochlorine Pesticide Contamination of Ground Water in the City of Hyderabad. *Environ int. 2006, feb; 32(2):244-7. [Environment international]: Environ Int*.
<u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: FATE.

ABSTRACT: Organochlorine pesticides are ubiquitous and persistent organic pollutants used widely throughout the world. Due to the extensive use in agriculture, organic environmental contaminants such as HCH, DDT along with other organochlorine pesticides are distributed globally by transport through air and water. The main aim of present study is to determine contamination levels of organochlorine pesticides in the ground water of Hyderabad City. Water samples were collected from 28 domestic well supplies of the city. For this study, random sampling technique was applied, all the samples were collected in high purity glass bottles and refrigerated at 4 degrees C until analysis. Solid Phase Extraction (SPE) is used for the extraction of organochlorine pesticide residues in water sample. The collected water samples were pre-

filtered through a 0.45 microg glass fiber filter (Wattman GF/F) to remove particulate matter and were acidified with hydrochloric acid (6N) to pH 2.5. Methanol modifier (BDH, for pesticide residue analysis, 10 mL) was added to water sample for better extraction. SPE using pre-packed reversed phase octadecyl (C-18 bonded silica) contained in cartridges was used for sample preparation. Prior to the extraction, the C-18 bonded phase, which contains 500 mg of bonded phase, was washed with 20 mL methanol. The sample was mixed well and allowed to percolate through the cartridges with flow rate of 10-15 mL/min under vacuum. After sample extraction, suction continued for 15 min to dry the packing material and pesticides trapped in the C-18 bonded phases were eluted by passing 10 mL hexane and fraction was evaporated in a gentle steam of Nitrogen. In all samples pesticide residues were analyzed by GC (Chemito-8510) with Ni63 ECD detector. Helium was used as carrier gas and nitrogen was used as make up gas. The injection technique was split/split less. All the samples analyzed were found to be contaminated with four pesticides i.e. DDT, beta-Endosulfan, alpha-Endosulfan and Lindane. DDT was found to range between 0.15 and 0.19 microg L(-1), beta-Endosulfan ranges between 0.21 and 0.87 microg L(-1), alpha-Endosulfan ranges between 1.34 and 2.14 microg L(-1) and Lindane ranges between 0.68 and 1.38 microg L(-1) respectively. These concentrations of pesticides in the water samples were found to be above their respective Acceptable Daily Intake (ADI) values for Humans.

ABSTRACT: PESTAB. The effects of Metathion E50 (50% fenitrothion), Phosphothion (50% malathion), Decemthion (20% phosmet), Acetellic 50EC (50% pirimiphos methyl), Nuvanol N50 WP (50% iodophenphos), Nexion 40WP (40% bromophos) and Ficam W (80% bendiocarb) on the larvae and imagines of the mosquito Culex pipiens Forsk., the fly Drosophil melanogaster, the toad Bufo bubo bufo Linn. and the crustacean Cyclops strennus strenuus were investigated. The active substances were added to the cultivation media for the insects, and to the water for the other two species to determine the lethal concentrations on the specimens. The effect of the insecticides on the zoocenosis of the biotopes of the mosquitoes was also determined. The concentrations at which 100% of the toads and crustaceans were killed were plotted and revealed that the applications of wide-spectrum insecticides are lethal to non-target organisms at levels intended for mosquito control.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Experiments were conducted in 1995 to determine the susceptibility Chrysomyia albiceps (Wiedeman, 1819), Cochliomyia macellaria (Fabricius, 1775) and Lucilia cuprina (Wiedemann, 1830) to eight insecticides. Wild flies were collected on Estacao Experimental para Pesquisas Parasitologicas W.O. Neitz - UFRRJ, and were

reared in the Laboratory of Entomology to the F2 generation for topical application tests. A two percent stock concentration for all insecticides was made on the basis of weight of technical insecticide per volume of acetone diluent. Reduced concentrations were mixed on a volume to volume basis. Flies to be treated were withdrawn from the holding cage with a modified vacuum cleaner, immobilized with CO2 and then treated with the insecticides using a Hamilton microsyringe. The mortality of the flies was registered after twenty-four hours of treatment. The regressions of dosage on mortality were made by the computerized probit analysis program POLO Probit or L

1185. Silva, Liana, Coutinho, Ana, Fedorov, Alexander, and Prieto, Manuel (2003). Solution conformation of a nitrobenzoxadiazole derivative of the polyene antibiotic nystatin: a FRET study. *Journal of Photochemistry and Photobiology B: Biology* 72: 17-26.
Chem Codes : Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Nystatin is a polyene antibiotic frequently applied in the treatment of topical fungal infections. In this work, a 7-nitrobenz-2-oxa-1,3-diazole (NBD) hexanoyl amide derivative of nystatin was synthesized and its detailed photophysical characterization is presented. The average conformation of the labelled antibiotic in tetrahydrofuran, ethanol and methanol was determined by intramolecular (tetraene to NBD) fluorescence resonance energy transfer measurements. At variance with the literature [Can. J. Chem. 63 (1985) 77-85], it was concluded that there is no need to invoke a solvent-dependent conformational equilibrium between extended and closed conformers of the antibiotic, because the mean tetraene-to-NBD separating distance was found to remain constant ([approximate]18 A) in all the solvents studied. In addition, the large solvent dependence of the fluorescence anisotropy observed for the non-derivatized nystatin, was rationalized on the basis of the prolate ellipsoidal geometry of the molecule. It was concluded that the rod shaped and amphipathic antibiotic remains monomeric in different solvents within the concentration range studied (2-20 [mu]M). Nystatin/ Polyene antibiotic/ Fluorescence/ FRET

Index Terms: Pesticides (organophosphorous; pesticides in household dust and soil and exposure pathways for children of agricultural families); Dust; Public health; Soil pollution (pesticides in household dust and soil and exposure pathways for children of agricultural families)
CAS Registry Numbers: 56-38-2 (Parathion); 86-50-0 (Azinphosmethyl); 732-11-6 (Phosmet); 2921-88-2 (Chlorpyrifos) Role: POL (Pollutant), OCCU (Occurrence) (pesticides in household dust and soil and exposure pathways for children of agricultural families) Children of agricultural families are likely to be exposed to agricultural chems., even if they are not involved in farm activities. This study was designed to det. whether such children are exposed to higher levels of pesticides than children whose parents are not involved in agriculture and whose homes are not close to farms. Household dust and soil samples were collected from children play areas from 59 residences in eastern Washington State (26 farming, 22 farmworker, and 11 nonfarming families). The majority of the farm families lived within 200 ft of an operating apple or pear orchard, whereas all ref. homes were located >=1/4 mi from an orchard. Four organophosphorous (OP) insecticides commonly used on tree fruit targeted for anal. were azinphosmethyl, chlorpyrifos, parathion, and phosmet. Pesticide concns. in household dust were significantly higher than in soil for all groups. OP levels for farmer/farmworker families ranged from nondetectable to 930 ng/g in soil (0.93 ppm) and from nondetectable to 17,000 ng/g in dust (17 ppm); all 4 OP compds. were found in 62% of household dust samples, and 2/3rds of the farm homes contained >=1 OP above 1000 ng/g. Residues were found less frequently in ref. homes, and all levels were <1000 ng/g. Household dust concns. for all 4 target compds. were significantly lower in ref. homes when compared to farmer/farmworker homes (Mann-Whitney U test; $p<0.05$). The results demonstrate that children of agricultural families have a higher potential for exposure to OP pesticides than children of nonfarm families in this region. Measureable residues of a toxicity I compd. registered exclusively for agricultural use (azinphosmethyl) were found in household dust samples from all study homes, that low-level exposure to such chems. occurs throughout the region. Phosmet features numerous degrdn. pathways induced by UV irradn. In this study, we focused on the reaction possibilities of phosmet in the presence of lipophilic substances with olefinic structure elements, as they are frequently found in animal fur lipids, esp. in wool wax. In the first step, simple models were employed to characterize the structural types of formed photoaddn. products. On irradn. in the presence of cyclohexene, three photoaddn. products were identified, a (4p + 2p) cycloaddn. product of phosmet and cyclohexene and two diastereoisomer carbinols. Likewise, in more sophisticated models employing fatty acid Me esters for irradn. expts., phosmet was readily photodegraded. In the presence of Me oleate, also 1:1 photoaddn. products could easily be identified by means of liq. chromatog.-mass spectrometry, using a stable isotope-labeled phosmet (15N-phosmet, 50 at. %) for the photolysis expts. To converge from models to the more complex natural environment of animal skin lipids, irradn. expts. of phosmet in the presence of wool wax were performed. After 24 h of irradn., only a remnant of 1.4% of the initial phosmet was detectable. Phosmet-oxon was detected in concns. up to 27.3 mol%. Induced by UV light, phosmet features numerous degrdn. pathways as well as photoaddn. reactions with lipid structure moieties. In model irradn. expts. of phosmet in mixts. of solvents (cyclohexane, cyclohexene, 2-propanol) and fatty acid Me esters (Me stearate, Me oleate, 12-hydroxymethyl stearate), both adjusted to the hydroxyl and iodine values of wool wax, half-lives were detd. to be approx. 7 and 16 h, resp. Irradn. of phosmet on crude sheep wool resulted in a degrdn. rate of 65% after 24 h. In tracer studies with stable isotope labeled phosmet ([15N]phosmet) in com. lanolin and on raw sheep wool, employing a sunlight simulator and natural sunlight, wool wax bound phosmet was formed. After extn. and measurement by elemental analyzer/isotope ratio mass spectrometry, d15N values of the phosmet-free wool wax fractions were notably increased as compared to the value of natural lanolin. Calcd. from the d15N values, an av. of 13.9/15.6% (sunlight simulator/natural sunlight) was bound to wool wax lipids after irradn. of thin films of com. lanolin. In expts. with sheep wool, 13.2 and 15.4%, resp., were detected as wax-bound. [on SciFinder (R)] 0021-8561 phosmet/ photolysis/ wool/ wax/ detn/ mass/ spectrometry

Citations: 25) Schwack, W; Tetrahedron Lett 1987, 28, 1869 The organophosphorus insecticide phosmet is used in plant protection as well as against parasites on animals. Phosmet showed numerous photoinduced reaction pathways, which first were studied in the presence of model environments for animal fur lipids (e.g., wool wax). The model solvents for satd. and unsatd. lipids were cyclohexane and cyclohexene, whereas methanol and 2-propanol were used as models for primary and secondary alc. moieties of lipids. The measured degrdn. rates over an irradn. period of 7 h in all solvents used were very similar (49-55%). The obtained photoproducts generally included phthalimide, N-hydroxymethylphthalimide, and N-methoxymethylphthalimide. Furthermore, depending on the solvent used, addnl. degrdn. products were detectable as N-isopropoxy- and N-methylphthalimide in the presence of 2-propanol and cyclohexene, resp. However, in the presence of cyclohexene, despite the similar turnover, distinctly lower concns. of photoproducts were found, indicating further still unknown degrdn. pathways. Irradiations in methanol with increasing percentages of water led to higher degrdn. rates; however, the products were found to be the same. Irradn. expts. with pure phosmet on silica TLC plates and glass surfaces resulted in degrdn. rates of 19 and 32%, resp., after 6 h. Thus, for the first time the photoinduced degrdn. of phosmet is strongly dependent on the chem. environment, affecting less the turnover than the photoproducts formed. The degrdn. behavior of phosmet on wool and in the presence of wool wax should be examd.. [on SciFinder (R)] 0021-8561 phosmet/ photolysis/ product/ solvent/ effect

1191. Singh, S. Santinath, Bohidar, H. B., and Bandyopadhyay, S. (2007). Study of gelatin-agar intermolecular aggregates in the supernatant of its coacervate. *Colloids and Surfaces B: Biointerfaces* 57: 29-36.
Chem Codes: Chemical of Concern: PSM Rejection Code: MODELING.

Intermolecular interaction leading to formation of aggregates between gelatin, a polyampholyte, and agar, a polysaccharide was studied in the supernatant of the complex coacervate formed by these biopolymers. Electrophoresis, laser light scattering and viscometry data were used to determine the interaction and the physical structure of these intermolecular soluble complexes by modeling these to be prolate ellipsoids of revolution (rod-like structures with well defined axial ratio and Perrin's factor). Solution ionic strength was found to reduce the axial ratio of these complexes implying the presence of screened polarization-induced electrostatic interaction between the two biopolymers. 1192. Sitsler, R. B. and Demers, S. K. (Remediation of Hanford's N-Reactor Liquid Waste Disposal Sites. *Health phys. 2003, feb; 84(2 suppl):s41-6. [Health physics]: Health Phys*.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: Hanford's N-Reactor operated from 1963 to 1987 generating approximately 9 x 10(7) m3 of radioactive and hazardous liquid effluent as a result of reactor operations. Two liquid waste disposal sites, essentially large trenches designed to filter contaminants from the water as it percolates through the soil column, were established to dispose of the effluent. The discharges to the sites included cooling water from the reactor primary, spent fuel storage, and periphery systems, along with miscellaneous drainage from reactor support facilities. Today, both sites are classified as Treatment Storage and Disposal Facilities under the Resource Conservation and Recovery Act of 1976, which makes them priority sites for remediation. The two sites cover approximately 4,100 m2 and 9,300 m2, respectively. Remediation of the sites requires removing a combined total of approximately 2.6 x 10(8) kg of contaminated soil and debris. Principal radionuclides contained in the soil/debris are 60Co, 137Cs, 239Pu, and 90Sr. Remediation of these waste sites requires demolishing concrete structures and excavating, hauling, and disposing of contaminated soils in work areas containing high levels of contamination and whole body dose rates in excess of 1 mSv h-1. The work presents unique radiological control challenges, such as minimizing external dose to workers in a constantly changing outdoor work environment, maintaining contamination control during removal of a water distribution trough filled with highly contaminated sludge, and minimizing outdoor airborne contamination during size reduction of highly contaminated pipelines. Through innovative approaches to dose reduction and contamination control, Hanford's Environmental Restoration Contractor has met the challenge, completing the first phase on schedule and with a total project exposure below the goal of 0.1 person-Sv.

Index Terms: Pesticides (carbamate and organophosphate, detn. of, using cobalt phthalocyanine-modified carbon paste electrode and cholinesterase enzyme membrane); Electrodes (carbon, cobalt phthalocyanine-modified, cholinesterase-covered, in detn. of pesticides)
CAS Registry Numbers: 3317-67-7 (Cobalt phthalocyanine) Role: BIOL (Biological study) (carbon electrode modified with, in amperometric detn. of pesticides); 9001-08-5 (Cholinesterase) Role: BIOL (Biological study) (cobalt phthalocyanine-modified carbon electrode covered with, in amperometric detn. of carbamate and phosphate pesticides); 62-73-7 (Nogos); 122-14-5 (Metathion); 732-11-6; 950-37-8 (Supracid); 2310-17-0 (Zolone); 13171-21-6 (Dimecron); 13593-03-8 (Ekalux); 22781-23-3 (Seedox); 23560-59-0 (Hostaquick); 29232-93-7 (Actellic); 55285-14-8 (Marshal) Role: ANT (Analyte), ANST (Analytical study) (detn. of, using cobalt phthalocyanine-modified carbon paste electrode and cholinesterase enzyme membrane) An amperometric biosensor for the detection and detn. of organophosphate and carbamate pesticides is based on a cobalt phthalocyanine-modified carbon paste electrode covered with a cholinesterase enzyme membrane. The electrode poised at +400 mV (vs. Ag/AgCl/3M KCl) oxidizes thiocholine formed by butyrylthiocholine hydrolysis in the glutaraldehyde-crosslinked cholinesterase layer. The activity of cholinesterase is non-competitively inhibited in the presence of pesticides. A linear relationship exists between the relative decrease in steady-state current after the addn. of a sample and the inhibitor concn. This method of evaluation allows the repetitive use of an enzyme membrane; twenty analyses can be carried out with a single cholinesterase membrane. The sensitivity varies from 0.181 (Hostaquick) to 0.00136 s-1 g-1 1 (Seedox); detection limits are 0.3 and 80 mg L-1, resp., for these two pesticides. The detn. of eleven pesticides is demonstrated. Descriptors: Puffinus pacificus
Abstract: Inputs of inorganic nutrients in 1992 from seabirds (white-capped noddy Anous minutus) and wedgetail shearwater (Puffinus pacificus), maximum of ca 80000 breeding pairs) are compared to inputs from humans (97700 person days) on Heron Island at the southern end of the Great Barrier Reef, Australia. We estimated that noddies deposited ca 107 t, and shearwaters ca 22 t, of fresh guano. The composition of fresh noddy guano was 7.3% nitrogen, 1.5% phosphorus, 60% moisture and 31.2% other substances. Assuming a similar composition for shearwaters, the total annual deposition of guano contained 9.4 t nitrogen and 1.9 t phosphorus. Experiments examining effects of ageing of guano indicated a large decrease in total nitrogen in guano under humid conditions over 4 d as a result of volatilisation of NH sub(3). Under natural conditions most of the deposited nitrogen is likely to be lost as NH sub(3) and a relatively small fraction of the soluble component leached into the cay, but the precise dynamics will depend on rainfall and wind patterns. Phosphorus was not volatilised from guano under any experimental conditions. Although inputs of nitrogen and phosphorus from human sewage into the cay system (ca 0.3 t of each) were much less than that from birds, all nutrients from humans are released in liquid form and percolate directly into the cay. Significant seasonal and tidal variations in standing concentrations of NH sub(3), oxidised forms of nitrogen (NO sub(2)+NO sub(3)), and PO sub(4) were detected in the water column around the island. Trends of higher mean concentrations of all nutrients in summer than in winter, and higher concentrations at low tide than at high tide except at sites close to the island where nutrient levels were high independent of tide, suggest that nutrients may be transported from guano on Heron Island into the water immediately surrounding the island. The exact fate and mechanisms of transport of all nutrients require further attention.

The interactions of over one hundred pesticides, including organochlorine, organophosphorus and organonitrogen compds., in various solvents and vegetable and fruit exts. with the activated carbon membranes were studied. It was found that in general pesticides contg. benzene rings with small substituents interacted strongly with the carbon membranes when the pesticides were dissolved in acetone, acetonitrile or Et acetate. On the other hand, pesticides without benzene rings or with benzene rings contg. bulky substituents showed little or no interaction with the carbon membranes when dissolved in the above mentioned solvents. Addn. of toluene to solns. of pesticides in either acetone or acetonitrile was necessary to minimize these interactions. A simple cleanup procedure for fruits and vegetables, involving the filtering of a sample slurry in 25 toluene in acetonitrile through an activated carbon membrane, followed by concn. and injection into a gas chromatograph equipped with a mass selective detector was developed. Recovery data from spiked lettuce, green pepper, pear and lemon are presented as well as data from real samples. With a few exceptions, over one hundred pesticides were quant. (>80%) recovered using the novel procedure. [on SciFinder (R)] 0021-9673 pesticide/ detn/ fruit/ vegetable/ carbon/ membrane;/ chromatog/ gas/ pesticide/ fruit/ vegetable

(OCls), and polycyclic arom. hydrocarbons (PAHs) in bivalves cultured in the Ebro Delta. Species exhibiting a wide range of lipid contents, namely Mytilus galloprovincialis, Ostrea edulis, Crassostrea gigas, and Ruditapes decussata were selected. Analyses of OPs were performed by gas chromatog. (GC) with nitrogen-phosphorus detection, OCls were detd. by GC with electron capture detection, and total PAHs using a flow injection system with fluorescence detection. Residue analyses indicated differences among species, that were reduced when concns. were normalized to lipid content. A seasonal fluctuation of pollutants was also obsd. that was related to the biol. cycle of the organisms and to the management of the waters in the rice crop fields of the delta. Toxicity thresholds for bivalves were not reached; nevertheless, more sensitive species such as crustaceans could be potentially affected. Toxicol. implications to humans might be of concern during field treatments with pesticides. Solid-phase extn. of 0.5 mL of wine sample is followed by direct injection of 1 mL of the eluent onto a DB-5 MS gas chromatog. column followed by mass-selective detection using one target and two qualifier ions for each pesticide. The extn. and injection steps are carried out with automatic instrumentation. Good resoln. of all compds. was achieved with a run-time approximating 23 min. Detection and quantitation limits were .apprx.2 mg/l and 10 mg/l, resp., with linear calibration curves up to 3 mg/l for most constituents. Recovery in half the compds. was >90%, and >80% in most of the remainder. Imprecision (relative std. deviation) was <10% for most pesticides and <18% in all. Further analytes can be added to the repertoire without difficulty. The method merits consideration together with four other multiresidue methods now available that offer similar anal. characteristics, slower run-times, and a different selection of analytes. The prepn. of samples included extn. by acetone and dichloromethane and cleaned up by gel permeation chromatog. and solid phase extn. (SPE) tube. The target analytes were detd. by gas chromatog.-mass spectrometric detector with selected ions mode (GC-MS/SIM). The method was validated by fortified at the level 0.02-0.20 mg/kg in leek. The av. recoveries of all analytes were between 70% and 113%, and std. deviations were below 13%. The limit of quantitation (LOQ) for most analytes was below 0.01 mg/kg. The method was used for other vegetables like spinach, cereal, capsicum, cucumber, tomato, eggplants,

etc. For those matrixes, the same concns. were fortified and got accepted recoveries and LOQ. [on SciFinder (R)] 0956-7135 pesticide/ leek/ vegetable/ gel/ permeation/ chromatog/ extn/ GCMS

The study focused on the fast sepn. and detn. of target analytes. By optimizing the chromatog. condition and selecting specific ions of analytes, all analytes were detd. by gas chromatog./ion-trap mass spectrometry in selective ion storage mode (GC-MS/SIS) within 35 min. The sample was extd. by dichloromethane and acetone, cleaned up by graphitized carbon black (GCB) solid-phase tubes. The limit of quantitation (LOQ) for most analytes was 0.01 mg/kg. The procedure involves the use of com. prepd. silica gel 1B Baker-flex plates and developing with 2,2,4-trimethylpentane:methyl cyclohexane:hexyl alc.:acetone (18:9:9:9). The pesticides are located by spraying with ammoniacal $AgNO_3$ soln. in acetone followed by exposure to longwave UV light. The method does not sep. ethion and phorate from each other. A method is also reported for the TLC sepn. of ethion from phorate in the presence of the other 6 pesticides using solvent system 2,2,4-trimethylpentane:hexane:$CHCl_3$ (18:18:12) on silica gel 1B Baker-flex plates. 1206. South, D. B. and Zwolinski, J. B. (1996). Chemicals Used in Southern Forest Nurseries. *Southern journal of applied forestry* 20: 127-135.
Chem Codes: Chemical of Concern: PSM Rejection Code: SURVEY.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Large-scale tree planting programs have placed a tremendous pressure on nursery managers to supply unprecedented numbers of seedlings. Inclusion of chemicals into seed production regimes have made it possible for southern pine nurseries to be the most productive in the world, in terms of both output per nursery and average cost per seedling. Nursery managers in the South rely on the use of fertilizers, fumigants, and pesticides to help keep production costs low. Judicious use of fertilizers can reduce the production of cull seedlings as well as increase field growth after outplanting. It has been our experience that

investing in the use of pesticides and inorganic fertilizers provides a high rate of return for the nursery manager.

Most epidemiol. studies of the health effect of pesticides have been based on self-reported information. However, detailed information on past pesticide use is difficult to reconstruct. This is a current study conducted among pregnant mothers attending a delivery care and perinatal program at a public hospital. The study investigates biomarkers of early effects in placentas from women living in an area with an intensive use of pesticides in the northern part of Patagonia, province of Rio Negro, Argentina, and it assesses the consistency of the information provided by self-reports. The study confirms that placental

acetylcholinesterase and catalase activities are significantly assocd. with periods of organophosphorus pesticides application, while glutathione S-transferase is not affected. The authors found a pos. correlation between environmental exposure to organophosphorus pesticides and carbamate insecticides and newborn head circumference. The findings provide a further indication of a link between placenta acetylcholinesterase and catalase activity and prenatal exposure to pesticides in population studies. Both placenta enzymes may be used as biomarkers in health surveillance programs for early diagnosis of exposure-related alterations produced by organophosphorus pesticides and carbamate pesticides. Pesticides concn. (10 mM) was used for in vitro incubations of cell-free homogenates labeled with 32P orthophosphate. Heptachlor (HC) and dichloro-diphenyl-trichloroethane (o-p' DDT) increased phosphatidyl-inositol, phosphatidylinositolphosphate, and phosphatidyl-inositolbiphosphate phosphorylation while azinphosmethyl (AM) increased phosphatidylinositolbiphosphate labeling. Decreased 32P incorporation in phosphatidylinositol was found with phosmet (PM), AM, and chlorpyriphos (CHL). The effects of these xenobiotics on PI4-kinase activity using different subcellular fractions were also examd. Both type of pesticides affected the postmembrane supernatant enzyme activity. A biphasic effect on membrane and nuclear PI4-kinase activity was seen with HC. The strongest effect found was seen with o-p' DDT in nuclear kinase activity while substantial changes were also obsd. in membrane. These data demonstrate the sensitivity of human placental PI4-kinase to pesticides currently found in human tissues and suggest deleterious consequences in different processes regulated by 4-phosphoinositides. ABSTRACT: PESTAB. Preliminary survey information on the organophosphorus pesticide industry wastewater streams and analytical methods to monitor levels of organic compounds present in these streams are presented. The identification and quantification of organophosphorus compounds was emphasized, but non-phosphorus chemicals were also included in the survey. A secondary goal of the program was to use the survey information to evaluate the efficiency of various waste treatment processes. The wastewater from five pesticide plants that produced 8 organophosphorus pesticides was sampled, The pesticides were diazinon, methyl parathion, azinophos-methyl, disulfoton, fonofos, phosmet bensulfide, and EPN. The 116 compounds identified included organophosphorus pesticides, related organophosphorus esters, organophosphorus acids, volatile organic compounds, thiocarbamate pesticides, triazine herbicides, and miscellaneous extractable process chemicals, by-products, and compounds of unknown origin. ABSTRACT: Filling and cleaning of pesticide sprayers presents a potential risk of pollution of soil and water. Three different solutions for handling sprayers have been suggested: Filling and cleaning in the field, filling and cleaning on hard surfaces with collection of the waste water, and filling and cleaning on a biobed, which is an excavation lined with clay and filled with a mixture of chopped straw, sphagnum and soil with turf on top, and with increased sorption capacity and microbial activity for degradation of the pesticides. In the present study the degradation and leaching of 21 pesticides (5 g of each) was followed in an established full-scale model biobed. Percolate was collected and analysed for pesticide residues, and the biobed material was sampled at three different depths and analysed by liquid chromatography double mass spectrometry (LC-MSMS). During the total study period of 563 days, no traces of 10 out of 21 applied pesticides were detected in the percolate (detection limits between 0.02 and 0.9 microg l(-1)) and three pesticides were only detected once and at concentrations below 2 microg l(-1). During the first 198 days before second application, 14% of the applied herbicide bentazone was detected in the leachate with maximum and mean concentrations of 445 and 172 microg l(-1), respectively. About 2% of the initial mecoprop and fluazifop dose was detected in the percolate, with mean concentrations of 23 microg l(-1), while MCPA and dimethoate had mean concentrations of 3.5 and 4.7 microg l(-1), respectively. Leachate concentrations for the remaining pesticides were generally below the detection limit (0.02-0.9 microg l(-1), below 1% of applied). Sorption studies of five pesticides showed that compounds with a low K(d) value appeared in the leachate. After 169 days, all pesticides in the biobed profile were degraded to a level below 50% of the calculated initial dose. Pesticides with K(oc) values above 100 were primarily found in the uppermost 10 cm and degraded slowest due to the low bioavailability. The 11 most degradable pesticides were all degraded such that less than 3% remained in the biobed after 169 days. Following second pesticide application of the biobed, leachate was sampled 215 and 365 days after the treatment. This showed the same pesticides to be leached out and at concentrations comparable to those of the first treatment. The same pesticides as after the first treatment were retained in the biobed.

ABSTRACT: PESTAB. A method for calculating a re-entry standard for work areas treated with pesticides is described. The calculations are based on the assumption that pesticides can enter workers not only via inhalation, but also dermally. These combined amounts of pesticides are then compared with the maximum permissible concentration. This approach was used to determine re-entry rates for a number of organochlorine [Kelthane (dicofol)] and organophosphorus [Rogor (dimethoate), Metaphos (methyl parathion), and Phthalophos (phosmet)] pesticides used in vineyards, orchards, and sugar beet fields. The re-entry periods for Phthalophos, Methylmercaptophos (demeton-O-methyl), and Intrathion (thiometon) are 7, 12, and 10 days, respectively.

Abstract: Pollen morphology was studied in 72 species and 20 genera of the zygomorphic-flowered Solanaceae (tribe Salpiglossideae as traditionally defined, the 'basal' nightshades), inclusive of their putative relatives. Results are compared with two markedly different current treatments of taxonomic relationships within this heterogenous group. Fifteen principal pollen types are recognised based on grain size, shape, aperture type, features of sculpturing, exine stratification and dispersal mode. Pollen grains may be 3-7 zonocolpate to colporate and oblate-prolate, with polar axis measurements ranging from 15 (mu)m to more than 60 (mu)m. In most taxa the exine is characterised by a reticulate ornamentation pattern, but in others it is rugulate,

striate, punctate or micoechinate. Tetrahedral tetrads (acalymmate) were observed in species of four genera - Bouchetia, Nierembergia, Reyesia and Salpiglossis - with the walls of adjacent monads linked by direct exinal bridges. Palynological evidence does not appear to support present generic limits, and a preliminary set of taxonomically and potentially phylogenetically useful pollen characters is presented. A multiresidue method for anal. of 90 pesticides with different physico-chem. properties in fruits and vegetables was developed. The method involves a rapid and small-scale extn. procedure with acetone using vortex mixing. Solid-phase extn. (SPE) on a highly cross-linked polystyrene divinylbenzene column (LiChrolut EN)

was used for clean-up and pre-concn. of the pesticides from the water-dild. acetone exts. For most fruit and vegetable samples this partial clean-up was sufficient, but some of them with more co-extg. substances need further clean-up (cereals, spinach, carrots, etc.). Diethylaminopropyl (DEA) modified silica was used for efficient removal of interferences caused by various org. acids, sugars, etc. The pesticide residues were detd. by gas chromatog. with a mass selective detector (GC-MS). The majority of pesticide recoveries for various fruits and vegetables were >80% in the concn. range from 0.01 to 0.50 mg/kg, except for the most polar pesticides (methamidophos, acephate, omethoate) which cannot be detd. by this method. The limit of quantitation for most of the pesticides was 0.01 mg/kg with majority of relative std. deviations (R.S.D.s) below 10%. Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. To demonstrate the contribution of atmospheric ammonium to soil acidification in acid forest soils, a field study with 15N-ammonium as tracer was performed in an oak-birch forest soil. Monitoring and analysis of soil solutions from various depths on the 15N-ammonium and 15N-nitrate contents, showed that about 54% of the applied 15N-ammonium was oxidized to nitrate in the forest floor. Over a period of one year about 20% of the 15N remained as organic nitrogen in this layer. The percentage 15N enrichment in ammonium and nitrate were in the same range in all the forest floor percolates, indicating that even in extremely acid forest soils (pH < 4) nitrate formation from ammonium can occur. Clearly, atmospheric ammonium can contribute to soil acidification even at low soil pH.

During application of multimethod S 19 (DFG Pesticide Commision) to onion and leek samples, GC-ECD (gas chromatog.-electron capture detection) anal. is difficult as most of the pesticide peaks are overlapped by matrix compds. Two-dimensional capillary-GC using the techniques of heart-cutting and backflushing makes it possible to transfer small fractions or even single peaks to a second column where all relevant pesticides can be sepd. from their overlapping matrix compds. Ni- and P-contg. pesticides in onion and leek samples were identified by selective detectors (N-P and flame photometric) without any problem. Capillary columns (SE-54, SE-30, OV-101) were used to sep. many commonly used insecticides. Chem. ionization with the simultaneous recording of pos. and neg. ions gave highest detection sensitivity for all 72 compds. studied. A selection of three ions was made for each pesticide and the parameters were optimized to gain highest detection sensitivity. The method was validated with food samples from a routine monitoring program. The influence of different ionization parameters on the total ion current and the relative intensities of the various fragment ions was studied. Few fragment ions were obsd., although they were characteristic for the class of compd. The occurrence of the mol. anion is strongly dependent on the mol. structure and its ability to stabilize the radical formed in the primary electron capture reaction by charge delocalization. Neg.-ion mass spectrometry with multiple ion detection may be a valuable tool for residue anal. in food and environmental samples. By means of live chromatog. applying the pneumatic switching technique of D. R. Deans (1968), unequivocal identification of 57 organophosphorus pesticides in food samples is achieved at trace concns. The instrument is equipped with only 1 injection port and 1 flame photometric detector. On-line data processing is very helpful, esp. in calibration and checking the system's reliability with the multitude of test compds. The complete pesticide residue anal. including clean-up of .apprx.6 food samples can be completed by 1 person in 8 h. (Prothiofos) Role: ANT (Analyte), ANST (Analytical study) (detn. of, by gas chromatog., using different injection modes) Three different injection modes were compared for the anal. of organophosphorus pesticides. Cold splitless injection with a programmed temp. vaporization (PTV) is of great potential for residues anal. Results with on-column injection of thermolabile and polar compds. as trichlorfon cannot be matched by PTV injection but, in comparison to hot-splitless technique, substance losses were considerably lower. Reproducibility of PTV sampling lies between that of the on-column and the hot-splitless techniques. Relative peak areas and std. deviations of 23 pesticides applying different injection modes are tabulated. [on SciFinder (R)] 0344-7138 pesticide/ residue/ gas/ chromatog/ injection/ mode

Using a capillary column, mass spectra of good quality were produced with 10 or 20 ng of each pesticide. Seventy-two compds. were not only identified at this concn. with the PBM (probability based matching) search routine in the NBS library, but also remarkably with the best fit in the corresponding hit list. Lower concns. can be detected only with selected ion monitoring (SIM). A mixt. of 18 chlorinated pesticides was added to green pepper at the 10 ppb level. All compds. were detected with SIM using special time programming in one gas chromatog. anal. The detection sensitivity of the mass selective detector in SIM mode approaches that of established selective detectors. The reliability of the results with

respect to the identity of a pesticide residue, however, is orders of magnitude better. Therefore, this detector is a valuable tool for performing confirmatory anal. [on SciFinder (R)] 0021-9673 pesticide/ residue/ gas/ chromatog/ mass/ spectrometry

A method for multiresidue pesticide anal. in food is described. After a conventional clean-up, gas chromatog. anal. is performed in a gas chromatograph equipped with 2 fused-silica capillary columns coated with methylsilicone SP 2100 and methylphenylsilicone OV-17. The effluent from each column is split to electron capture and detectors, which are connected to a dual channel integrator. Therefore, from each gas chromatog. run parallel records of signals from the 2 detectors are obtained. Calibration of the system is carried out for the SP 2100 column with 3 test mixts. covering all pesticides. Addnl., 4 internal stds. are included, responding to the electron-capture detector and other 2 to the N-P detector. Automated anal. is performed with test matter and food samples on the SP 2100 column overnight as a screening procedure. After selection of pos. samples a confirmatory test and quantitation are carried out manually applying appropriate test mixts. according to the results of the screening runs. (GC). The heteroatoms N, Cl, P, S, Br and F, which are important elements in pesticide residue anal., are of major interest. A main drawback of AED is its lower sensitivity with respect to other selective detection methods used in pesticide residue anal. such as electron-capture and N-P detection. This holds true esp. for the important N trace. For this reason, more sensitive detection can be achieved by injection of larger vols. or higher concns. of sample exts., because matrix compds. were usually registered only in the C, H, O traces. This paper focuses on recent developments from the authors' lab. to demonstrate the feasibility of screening analyses with the identification of pesticide residues down to the 0.01 ppm concn. level in plant foodstuffs. This has been achieved by means of automated large vol. injection with programmed-temp. vaporization and solvent venting as well as careful optimization of make-up and reactant gases with AED. Clean up follows the principle of multimethod S19 of the Deutsche Forschungsgemeinschaft in a reduced procedure. After elimination of lipids and waxes by gel permeation chromatog., exts. from 10 g of the food samples were concd. to 200 ml, of which 12.5 ml were introduced into the GC-AED system. Two analyses were usually performed with the element traces of S, P, N, and C in the 1st run and Cl and Br in the 2d run. F and O were not detected in any screening analyses. The method has proved to be of great value esp. with \"problem foodstuffs\". The limits of detection were detd. for 385 pesticides and are presented together with their retention data. Both columns were connected by effluent splitting to the selective flame-photometric and electron-capture detectors, which were linked on-line to independent data processing channels. About 100 halogenated and organophosphorus pesticides, together with 3 internal stds., were screened on the first column with methylsilicone as the stationary phase. The compds. were recognized by their retention data and response to the 2 selective detectors. In a 2nd anal., peaks eluted from the 1st column were transferred by pneumatic switching to the 2nd column with phenylcyanopropylmethylsilicone as the stationary phase. This cutting of narrow fractions could be executed with high accuracy and reproducibility (live chromatog.) by using time programming of the cutting valve. The final identification of all investigated pesticides was achieved by evaluating the set of linked retention data and, addnl., the response ratio of the 2 detectors characteristic for each compd. Application of the method to 2 real food samples, fortified with chlorinated and organophosphorus pesticides, was demonstrated. This paper focuses on recent developments in the author's lab. and reports on the \"ultimate\" anal. scheme which has evolved over the last 20 yr. This demonstrates the feasibility of screening analyses for pesticide residue identification, mainly by full scan GC-MS, down to the 0.01 ppm concn. level in plant foodstuffs. It is based on a miniaturized DFG S19 extn. applying acetone for extn. followed by liq.-liq. extn. with Et acetate-cyclohexane followed by gel permeation chromatog. The final chromatog. detn. is carried

out with a battery of 3 parallel operating gas chromatog. systems using effluent splitting to electron-capture and nitrogen-phosphorus detection, one with a SE-54 the other with a OV-17 capillary column and the 3rd one with a SE-54 capillary column and mass selective detection for identification and quantitation. The method is established for monitoring >400 pesticides amenable to gas chromatog. These pesticide residues are identified in screening analyses by means of the dedicated mass spectral library PEST.L contg. ref. mass spectra and retention times of >400 active ingredients and also metabolites applying the macro program AuPest (Automated residue anal. on Pesticides) for automated evaluation which runs with Windows based HP ChemStation software. The 2 gas chromatog. systems with effluent splitting to electron-capture and nitrogen-phosphorus detection are used to check the results obtained with the automated GC-MS screening and also to detect those few pesticides which exhibit better response to electron-capture and nitrogen-phosphorus detection than to mass spectrometry in full scan. Patent Application Country: Application: GB Granular pesticides are prepd. by spraying relatively nonadsorbent particles into the pesticidal soln., followed by backdrying with a finely divided, highly adsorbent powder, such as Ca silicate, and by repeating the process until the granules are formed with the requisite amt. of pesticide around the nonadsorbent carrier. Thus, 86.5 g CaCO3 chips are treated with 1/3 of a soln. of 5 g N-(mercaptomethyl)phthalimide-S-(O,O-dimethylphosphorodithioate) [732-11-6] in 4 g heavy aromatic naphtha and 1 g of a tall oil fatty acid, followed by the addn. of 1 g Ca silicate. The remaining 2/3 of the soln. were added in 2 portions, together with 1 g Ca silicate each, to give a free-flowing granular product. Patent Application Country: Application: IL Thionophosphates R2OP(S)(OR)OR1 (I) (where R = R1 = alkyl; R2 = Ph or alkylphenyl) are synergists for N-(mercaptomethyl)phthalimide-S-(O,O-dimethylphosphorodithioate) (II) [732-11-6]. Thus, a compn. contg. I, R = Me; R1 = Me, R2 = phenyl [33576-92-0] and II had an LD50 of 30 mg/25 houseflies, II without the synergist had an LD50 of 5000 and the synergist alone was >104-fold less toxic in studies with houseflies. Similar results were obtained with the other synergists. Some prepn. data for the synergists is given. Patent Application Country: Application: GB The insecticidal activity of N-(mercaptomethyl)phthalimide-S-(O,O-dimethylphosphorodithioate) (I) [732-11-6] was increased by including a phosphorothioate (RO)P(S)(OR1)(OR2) (R and R1 = alkyl; R2 = aryl) as activator. (MeO)P(S)(OMe)(OPh) (II) [33576-92-0] was prepd. by reaction of PhOH with O,O-di-Me phosphorochloridothioate [2524-03-0], and a soln. of II (500 mg/mL) was mixed with a soln. of I (100 mg/mL) in the ratio of 5:1. The LD50 of I solns. towards houseflies was reduced by inclusion of II from 5000 to 30 mg, i.e. an activating factor of 166.7. Abstract: Mine reclamation with biosolids increases revegetation success but nutrient addition well in excess of vegetation requirements has the potential to increase leaching of NO sub(3) and other biosolids constituents. A 3-yr water quality monitoring study was conducted on a Pennsylvania mine site reclaimed with biosolids applied at the maximum permitted and standard loading rate of 134 Mg ha super(-1). Zero-tension lysimeters were installed at 1-m depth 1 yr before reclamation: three in the biosolids application area, one in a control area (no biosolids). Before reclamation, all water samples had pH in the range 4.7 to 6.2, acidity <20 mg L super(-1), and very low levels of all other measured parameters. Following reclamation, percolate water in the biosolids-treated area had lower pH and greater acidity than the control area. Acidity was greatest during the first winter following biosolids application, decreased during the spring, and showed a similar pattern but with much smaller concentrations the second year. Maximum first-year leachate NO sub(3) concentrations were similar to 300 mg L super(-1) and half as large the second year. Estimated inorganic N leaching loss during the first 2 yr after biosolids application was 2327 kg N ha super(-1). Aluminum, Mn, Cu, Ni, Pb, and Zn followed similar leaching patterns as did acidity, and their mobilization appeared to be the result of the increased acidity. These results indicate that large applications of low-C/N-ratio biosolids could negatively impact area water quality and that biosolids reclamation practices should be modified to reduce this possibility.

Citations: Zabik, M; Journal of Agricultural and Food Chemistry 2000, 48, 4199 During 3 years of a monitoring program, 522 samples of fresh apples, 6 brands of fruit purees and various types of fruit baby food prepd. from these materials were analyzed. Each sample was examd. for the presence of 86 GC amenable pesticide residues. The reporting limits of the procedure employed for sample analyses were in the range 0.003-0.01 mg kg-1. Pesticide residues were detected in 59.5% of the samples of fresh apples. However, max. residue levels (European Union MRLs) were exceeded only in 1.4% of samples. The levels of residues in 'pos.' fruit purees were substantially lower, overall with residues detected in 33% of samples. Fruit baby food represented the commodity with the lowest incidence of residues being detected in only 16% of samples. The 0.01 mgkg-1 MRL was exceeded in 9% of these products. Multiple residues were found in 25% of fresh apples and in 10% of fruit purees. None of fruit baby food samples contained more than a single residue. Organophosphorus insecticides and fungicides representing phtalimides, sulfamides and dicarboximides were the most frequently found residues. To obtain more knowledge on the fate of residues during fruit baby food prodn., processing expts. employing

apples with incurred residues (fenitrothion, phosalone and tolylfluanid) were conducted. Washing of apples did not significantly reduce the content of pesticides. Steam boiling followed by removal of peels/stems was identified as the most efficient steps in terms of residues decrease (phosalone) or complete elimination (fenitrothion and tolylfluanid). ABSTRACT: PESTAB. Definitions are offered of mutagenesis, teratogenesis and the relationship between teratogenesis and carcinogenesis. Studies related to specific pesticides are reviewed and the significance of their findings reported. Specific chemicals discussed include DDT, methoxychlor, aldrin/dieldrin, Kepone (chlordecone), chlordane and heptachlor, mirex, lindane, toxaphene, dichlorvos, malathion, parathion, trichlorfon, phthalophos, and crufomate. Other agents also discussed include carbaryl, piperonyl butoxide, and pyrethrum.

1237. Stevik, Tor Kristian, Ausland, Geir, Jenssen, Petter Deinboll, and Siegrist, Robert L. (1999). Removal of E. coli during intermittent filtration of wastewater effluent as affected by dosing rate and media type. *Water Research* 33: 2088-2098.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA, EFFLUENT.

Wastewater effluent dosing rates of 25 and 50 mm/day were intermittently applied in eight daily doses of 3.125 or 6.25 mm each, to 15-cm diameter 80 cm high columns packed with two types of Light Weight Aggregates (LWA) and one type of activated carbon aggregates. After three months of wastewater effluent application at 25 mm/day to stabilize the filter systems, Escherichia coli was spiked once each day onto the surface of the columns and wastewater effluent was applied at 25 mm/day for the months. The same procedure was repeated for effluent application rate of 50 mm/day. During operation, hydraulic behavior was monitored by moisture tensiometers located 5, 10, 20 and 40 cm below the filter surface as well as by radiotracer studies. Removal behavior was assessed by sampling and analysis of the column percolate and media within the column. The removal of E. coli was decreased as a result of increasing the dosing rate for all three media. In all media, the highest removal rates were observed in the upper part of the columns. Sorption head measurements showed that each effluent dose rapidly penetrates through the upper part of the filters, until a steady state, unsaturated flow was established in the lower sections. Different flow patterns were observed for the two dosing rates. For the dosing rate of 50 mm/day, the flow was penetrating faster, and to a deeper level before establishing steady unsaturated flow. Fast flow through the upper part of the filter, where the bacterial removal is most effective, may explain the significantly lower removal for the dosing rate of 50 mm/day. The dynamic behavior of the filter columns showed that most of the water movement took place right after dose application, during intermittent dosing. This indicates that dose size may be just as important for bacterial removal as the daily dosing rate. ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Part of an investigation of data collection methods in epidemiologic studies of farmers evaluated exposures received by farmers from the application of insecticides to animals. Twenty farmers were monitored during a normal application using a fluorescent dye surrogate for the active ingredient (AI). Two exposure measures were estimated, AI concentration and the time-weighted average for the application period (TWAa). Four application methods were used: high- (n=5) and low-pressure (n=3) spraying exposed

farmers (18 mug) and more than two-thirds of the farmers wearing this amount of clothing had nondetectable exposures. In contrast, clothing providing little or no protection was associated with a significantly higher ($p < 0.01$) average AI concentration (4420 mug), and less than a third of the farmers with this degree of protection had nondetectable exposures. Poor work practices (leaking equipment, contact with wet animals or fences, and back splash) were associated with

Farmers were monitored using dermal patches, gloves, and air sampling media during normal activities of applying phosmet to swine for insect control. Exposures were measured on the clothing (outer), under the clothing (inner), on the hands, and in the air. Exposure determinants were identified, and a questionnaire on work practices was administered. The outer exposure was 79 mg/h, whereas the inner exposure was 6 mg/h. The hand exposure was 534 mg/h, and the air concn. was 0.2 mg/m3. Glove use was assocd. with the hand and total dermal exposure levels, but no other determinant was assocd. with any of the exposure measures. The penetration through the clothing was 54%, which dropped to 8% when the farmers wearing short sleeves were excluded. The farmers reported 40 h a year performing insecticide-related tasks. Thus, farmers who applied phosmet to animals had measurable exposures, but the levels were lower than what was seen in other pesticide applications. Inhalation exposures were insignificant when compared with dermal exposures, which came primarily from the hands. Clothing, particularly gloves, provided substantial protection from exposures. No other exposure determinant was identified. [on SciFinder (R)] 0355-3140 phosmet/ air/ pollution/ swine/ farmer/ occupational/ exposure

Biochemistry and Biophysics 122: 32-39.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Graded self-hydrolysis of commercial bovine heparin produced samples of varying anticoagulant activity. The hydrolysis results in desulfation, which is accompanied by decrease in (a) sedimentation coefficient, (b) intrinsic viscosity when measured in water, and (c) axial ratios, a/b, if a prolate ellipsoid model is assumed. Intrinsic viscosities obtained in 0.5 NaCl were relatively unchanged for the hydrolyzed samples. The drop in molecular weight during inactivation is due to desulfation and not to depolymerization. Hydrolysis results in both O- and N-desulfation, the latter to a greater extent than the former. The data suggest that degree of sulfation and size and/or shape confer on heparin its biological activity. http://www.sciencedirect.com/science/article/B6WB5-4DV04VM-5H/2/70fe2fe7ce4385ae0e1d43cbc1ec7d8e

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Objectives: An epidemiological study of 90 male pesticide applicators licensed in New York was conducted to investigate the effect of exposure to organophosphate pesticides on the peripheral nervous system. Methods: A cohort of farmers and pesticide applicators from New York State were questioned off season (November 1988-February 1989) and again during the spraying season (April 1989-August 1989) about the presence of several acute signs and symptoms. Short term exposure was validated by measuring the concentration of dimethylthiophospahte (DMTP), a metabolite of guthion, in urine. Chronic signs of subtle peripheral nerve damage were determined by vibration threshold sensitivity of the farmers and applicators tested during November 1988-February 1989 and compared with controls drawn from the general population who were tested during the same time period the next year (November 1989-February 1990). Vibration threshold sensitivity was determined for both the hands and fe

1244. Stone, D. B., Timmins, P. A., Schneider, D. K., Krylova, I., Ramos, C. H. I., Reinach, F. C., and Mendelson, R. A. (1998). The effect of regulatory Ca2+ on the in situ structures of troponin C and troponin I: a neutron scattering study. *Journal of Molecular Biology* 281: 689-704.
Chem Codes: Chemical of Concern: PSM Rejection Code: MODELING.

The effects of regulatory amounts of Ca2+ on the in situ structures of troponin C (TnC) and troponin I (TnI) in whole troponin have been investigated by neutron scattering. In separate difference experiments, 97% deuterated TnC and TnI within whole troponin were studied +/-Ca2+ in 41.6% 2H2O buffers in which protonated subunits were rendered "invisible". We found that the radius of gyration (Rg) of TnI decreased by [approximate]10% upon addition of regulatory Ca2+indicating that it was significantly more compact in the presence of Ca2+. The apparent cross-sectional radius of gyration (Rc) of TnI increased by about 9% when regulatory Ca2+ was bound to TnC. Modeling studies showed that the high-Q scattering patterns of TnI could be fit by a TnI which consisted of two subdomains: one, a highly oblate ellipsoid of revolution containing about 65% of the mass and the other, a highly prolate ellipsoid of revolution consisting of about 35% of the mass. No other fits could be found with this class of models. Best fits were achieved when the axes of revolution of these ellipsoids were steeply inclined with respect to each other. Ca2+ addition decreased the center of mass separation by about 1.5 nm. The Rg of TnI, its high-Q scattering pattern, and the resultant structure were different from previous results on neutron scattering by TnI in the (+Ca2+) TnC[middle dot]TnI complex. The Rg of TnC indicated that it was elongate in situ. The Rg of TnC was not sensitive to the Ca2+ occupancy of its regulatory sites. However, Rc increased upon Ca2+ addition in concert with expectations from NMR and crystallography of isolated TnC. The present observations indicate that TnI acts like a molecular switch which is controlled by smaller Ca2+-induced changes in TnC. troponin structure/ Ca2+ switch/ regulation of muscle contraction/ neutron scattering

A modified longer and wider Storherr tube and heating assembly was used in this work and 3-mm.-diam. glass beads replaced the glass wool packing used in crop work. The work on oils was performed at 248 +- 3 Deg with a N flow of 600 ml./min. and injection of a sweeping solvent every 3 min. for 30 min. Phosphate pesticides were analyzed by gas chromatog. with a K thermionic detector and chlorinated pesticides were detd. by electron-capture gas chromatog., after a micro Florisil column was used to eliminate extraneous peaks. Recoveries of 10 phosphate pesticides from 9 edible oils ranged from 74 to 100% at fortification levels of 0.04 to 6.25 ppm.; av. recoveries for the individual pesticides were 90-9%. Av. recoveries for the chlorinated pesticides ranged from a low of 75% for Tedion to a high of 98% for endrin and dieldrin. Sensitivity of 0.01 is readily obtainable for compds. such as parathion and heptachlor epoxide. The sweep codistn. method is suitable for the rapid detn. of the 14 chlorinated and 10 organophosphate pesticides tested in edible oils. [on SciFinder (R)] 0004-5756 CHROMATOG/

ABSTRACT: There is much interest in the relationship of atmospheric nitrogen (N) inputs to ecosystem outputs as an indicator of possible "nitrogen saturation" by human activity. Longer-term, ecosystem-level mass balance studies suggest that the relationship is not clear and that other ecosystem processes may dominate variation in N outputs. We have been studying small, forested watershed ecosystems in five northern watersheds for periods up to 35 years. Here I summarize the research on ecosystem processes and the N budget. During the past 2 decades, average wet-precipitation N inputs ranged from about 0.1 to 6 kg N ha(-1) year(-1) among sites. In general, sites with the lowest N inputs had the highest output-to-input ratios. In the Alaska watersheds, streamwater N output exceeded inputs by 70 to 250%. The ratio of mean monthly headwater nitrate (NO3-) concentration to precipitation NO3- concentration declined with increased precipitation concentration. A series of ecosystem processes have been studied and related to N outputs. The most important appear to be seasonal change in hydrologic flowpath, soil freezing, seasonal forest-floor inorganic N pools resulting from over-winter mineralization beneath the snowpack, spatial variation in watershed forest-floor inorganic N pools, the degree to which snowmelt percolates soils, and gross soil N mineralization rates.

Citations: Wauchope, R; Rev Env Contam Toxicol 1992, 123, 1 Fisher's exact test was used to assess the relationship between self-reported health symptoms and indicators of exposure to organophosphate (OP) pesticides in 211 farmworkers in Eastern Washington. The health symptoms most commonly reported included headaches (50%), burning eyes (39%), pain in muscles, joints, or bones (35%), a rash or itchy skin (25%), and blurred vision (23%). Exposure to pesticides was prevalent. The proportion of detectable samples of various pesticide residues in house and vehicle dust was weakly assocd. with reporting certain health symptoms, particularly burning eyes and shortness of breath. No significant assocns. were found between reporting health symptoms and the proportion of detectable urinary pesticide metabolites. Certain self-reported health symptoms in farmworkers may be assocd. with indicators of exposure to pesticides. Longitudinal studies with more precise health symptom data are needed to explore this relationship further. Citations: Stevens, R; J Great Lakes Res 1989, 15, 377 Pesticides are heavily used for agricultural prodn. in the Great Lakes basin. Large-vol. samples, collected from 1994 to 2000 from lakes Ontario, Erie, Huron (including Georgian Bay), and Superior, were analyzed for neutral and phenoxy-acid herbicides and organophosphorus insecticides. A total of 39 pesticides from these 3 classes, including analytes and some metabolites, were measured. Six pesticides (barban, diallate-2, triallate, phorate, phosmet, disulfoton) were not detected. Atrazine, metolachlor, simazine, and

2,4-D were detected in >50% of samples. Highest max. concns. were obsd. for atrazine (1,039 ng/L), metolachlor (736 ng/L), and D-simazine (281 ng/L). No pesticide concns. exceeded water quality guidelines/criteria for protection of aquatic life and drinking water. Generally, an increasing concn. gradient from north to south was obsd. with Superior < Huron < Ontario < Erie. Spatial and seasonal variability of selected pesticides are discussed in relation to their use and application. [on SciFinder (R)] 0380-1330 pesticide/ water/ pollution/ Great/ Lake/ basin/ USA

1254. Su, Ping, Harvey, Melissa, Im, Hee J., and Dunn, Noel W. (1997). Isolation, cloning and characterisation of the abiI gene from Lactococcus lactis subsp. lactis M138 encoding abortive phage infection. *Journal of Biotechnology* 54: 95-104.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

Plasmid pND852 (56 kb) encodes nisin resistance and was isolated from Lactococcus lactis ssp lactis (L. lactis) M138 by conjugation to L. lactis LM0230. It conferred strong resistance to the isometric-headed phage [phi]712 and partial resistance to the prolate-headed phage [phi]c2. A 2.6 kb HpaII fragment encoding phage resistance was cloned into the streptococcal/Bacillus hybrid vector pGB301 to generate pND817. The mechanism of phage resistance encoded by pND817 involved abortive infection and this was illustrated by a reduction in burst size from 166 to 6 at 30[degree sign]C and from 160 to 90 at 37[degree sign]C. Partial resistance was therefore retained at 37[degree sign]C. DNA sequencing revealed that the abortive infection was encoded by a single open reading frame (ORF), designated abiI, encoding a 332 amino acid protein. Neither abiI nor the predicted product showed significant homology to any existing sequence in the GenBank database. Frame shift mutation at the unique EcoRI site within the ORF resulted in loss of the Abi+ phenotype, confirming that the ORF is responsible for the encoded phage resistance.

Some 131 heterogeneous chems. including medicals, pesticides, detergents, and org. solvents, were used in this study. The eye irritation ratings were made in three classes on the basis of the recovery time of corneal and conjunctival damages. Thirty-six descriptors were used to describe the mols. To correlate eye irritation ratings with the descriptors, a QSAR model was formulated by the adaptive least-squares method. A three-class discrimination was made as follows. Class I included 23 chems. which

induced the damages recovering within 24 h, class II included 64 chems. which induced the damages persisting for more than 24 h but recovering within 21 days, and class III included 44 chems. which induced the damages not recovering within 21 days. The discriminant function included 18 descriptors. The accuracy in classifying the chems. was 86.3% in the recognition and 74.0% in the leave-one-out prediction. These results suggest that QSAR anal. is valuable to predict the primary eye irritation of chems. [on SciFinder (R)] 0388-1350 chem/ structure/ toxicity/ eye/ irritation/ test

1256. Sukstanskii, Alexander L. and Yablonskiy, Dmitriy A. (2001). Theory of FID NMR Signal Dephasing Induced by Mesoscopic Magnetic Field Inhomogeneities in Biological Systems. *Journal of Magnetic Resonance* 151: 107-117.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

A theory of the NMR signal dephasing due to the presence of tissue-specific magnetic field inhomogeneities is developed for a two-compartment model. Randomly distributed magnetized objects of finite size embedded in a given media are modeled by ellipsoids of revolution (prolate and oblate spheroids). The model can be applied for describing blood vessels in a tissue, red blood cells in the blood, marrow within trabecular bones, etc. The time dependence of the dephasing function connected with the spins inside of the objects, si, is shown to be expressed by Fresnel functions and creates a powder-type signal in the frequency domain. The short-time regime of the dephasing function for spins outside the objects, se, is always characterized by Gaussian time dependence, se~exp[-[zeta]k(t/tc)2], with [zeta] being a volume fraction occupied by the objects, tc being a characteristic dephasing time, and the coefficient k depending on the ellipsoid's shape through the aspect ratio of its axes (a/c). The long-time asymptotic behavior of se is always "quasispherical"-linear exponential in time, se~ exp(-[zeta]Ct/tc), with the same "spherical" decay rate for any ellipsoidal shape. For long prolate spheroids (a/c)<<1, there exists an intermediate characteristic regime with a linear exponential time behavior and an aspect-ratio-dependent decay rate smaller than ([zeta]C/tc). http://www.sciencedirect.com/science/article/B6WJX-457VF81-2J/2/41d27d07db1ec3954382eb13e54f88d7

Abstract: A great deal of the pollutants have been produced by the civilized human by virtue of his input into industries and consequently the output being the release of pollutants into the aquatic ecosystem. Scientific studies confirm that different pollutants have varied impacts on the aquatic biota and in particular fishery resources that form a food resource to human. Thus it becomes increasingly apparent that industrialization and other multifaceted activities of human have caused aquatic pollution. India is one of the largest fish producing nations in the world ranking ninth among other nations. Almost all the pollutants interfere with the metabolism of the aquatic fauna including fish fauna. Pollutants exhibit lethality that is diversified in various organ systems. Respiratory changes include clogging of the gills due to the modification of bronchial cells by histopathological changes, whereas damage to haemopoietic tissue can lead to modification of the respiratory pigments of the blood and can decrease the oxyphoretic capacity of the blood.

Generally the pollutants percolate into the cellular level through the cell membrane and interact with cellular macromolecules to inhibit the essential cellular metabolism. Thus, measurement of sublethal responses at the cellular level could provide an insight for an assessment of water quality and environmental impact of pollutants. The present case study investigations discloses not only the effluents which cause imbalance in the brackish water ecosystem and shrimp inhabitation but also throws light on the effect of human health through the aquatic food chain.

(SPE) technique and using gas chromatog. detn. of organochlorine (OC), organophosphorus (OP) and synthetic pyrethroid pesticides residues in beef fat was studied. The group of pesticides was added to dissolved beef fat (0.5 g) and blended with 8% de-activation florisil. The florisil/fat mixt. was packed into disposable filtration columns. This column was tandem with an octadecyl SPE column and was eluted with acetonitrile. The pesticide residues were detd. by gas chromatog. with electron capture and flame photometric detectors. Three kinds (including OC, OP and synthetic pyrethroid) with a total of 71 pesticides (including their metabolites) were tested in this study. With the exception of isoxthion and flucythrinate with high recovery rates (122% +-13% and 137% +- 31%, resp.), according to the correlation coeffs. for the 71 extd. pesticide std. curves (ranging from 0.9915+-0.0176 to 0.9999+-0.0200, n = 5), av. recovery rate (ranging from 68+-9% to 117+-11%, n = 25 for each insecticide), inter-assay variability (ranging from 3+-3% to 17+-12%, n = 25 for each insecticide), infra-assay variability (ranging from 3 to 19%, n = 5 for each insecticide) indicated that the methodol. is acceptable for the extn., detn., and screening of theses residues in beef fat. The detection limits for OCs, OPs and synthetic pyrethroid pesticides are 2.apprx.21 ng/g, 6.apprx.31 ng/g and 3.apprx.118 ng/g, resp. Comparing with studies conducted by the National Anal. Ref. Lab. in Western Australia in the field of pesticide residue testing in beef fat, the results indicated that the present method could accurately measure commonly used pesticide chems. (SPE) technique. In the present procedures, samples were extd. with acetonitrile except for bivalve and cuttlefish samples. Mixed solvent of water, acetone and acetonitrile was added to bivalve prior to homogenization, whereas water was

needed in cuttlefish samples for blending. For both kinds of sample, an addnl. procedure of salting-out was needed during extn. Tandem SPE cartridges of C18 and aminopropyl, using acetonitrile as the only solvent, were used to clean up exts. from either method. A total of 91 pesticides in four major pesticide groups were tested in this study. Gas chromatog. (GC, equipped with electron capture detector and flame photometric detector) and high-performance liq.-chromatog. (HPLC) equipped with fluorescence detector were used for anal. The validation of the method was evaluated for each fishery product using samples spiked with all pesticide stds. at three concn. levels. The results indicated percentage of recovery ranged from 60% - 120% and coeffs. of variation < 20% for all but 10 of the pesticides analyzed (including 1-naphthol, 3-hydroxy carbofuran, aldicarb sulfoxide, heptachlor, trifuralin, acephate, dichlorvs, methamidophos, monocrotophos and omethoate). Residue extn. techniques described in this report are rapid and suitable for screening of pesticide residues in monitoring programs. ABSTRACT: PESTAB. A method is described for the detection and quantification of pesticides on silica gel chromatograms by in situ fluorometry. Simple organic salts are used to induce fluorescence in a number of pesticidal compounds. Intensified fluorescence is shown for one naturally fluorescent pesticide. Spectral data and instrumental limits of detection are given. Of the total of 64 pesticides tested, positive results were obtained for captan, devrinol (napropamide), difolatan, diquat, maretin (phosmet), menazon, naptalam, propyl isome, paraquat, and rotenone. (Author abstract by permission, supplemented.)

This study was undertaken with two soils of contrasting properties to det. the extent to which sorption and degrdn. of the insecticide might influence its potential to leach from soil into receiving waters. Two soils were used: a highly org., oxidic clay soil (Ferrosol) and a sandy soil low in org. matter (Podosol), sampled to 0.3 m depth. The extent of sorption and decompn. rate of a phosmet com. formulation were measured in lab. expts. Sorption followed a Freundlich isotherm at all depths. The Freundlich coeff. K was significantly correlated ($p = 0.005$) with org. C content in the Podosol, and significantly correlated ($p = 0.005$) with org. C and clay content in the Ferrosol. K was highest (48.8 L kg-1) in the 0- to 0.05-m depth of the Ferrosol, but lowest (1.0 L kg-1) at this depth in the Podosol. Degrdn. followed first-order kinetics, with the phosmet half-life ranging from 14 h (0-0.05 m depth) to 187 h (0.2-0.3 m depth) in the Ferrosol. The half-life was much longer in the sandy Podosol, ranging from 462 to 866 h, and did not change significantly with depth. Soil org. C and to a lesser degree clay content influenced phosmet sorption and degrdn., but the interaction was complex and possibly affected by cosolvents present in the com. formulation (Imidan EC 150). Other groups affected were gardeners (101), field workers exposed to pesticide residues (117), nursery and greenhouse workers (75), soil fumigators in agriculture (29), equipment cleaners and mechanics (28), tractor drivers and irrigators (23), workers exposed to drift (22), pilots (crop dusters) (17), and flaggers for aerial application (6). Most illnesses were a result of carelessness, lack of knowledge of the hazards, lack of safety equipment, and of the dry, hot conditions, which allow a buildup of pesticide-contg. dust on the crops and which mitigate against the use of protective clothing. 1268. Takahashi, K., Ishii, R., Iijima, M., and Hoshino, Y. (1995). Studies on Analysis of Organophosphorus, Pyrethroid and Organonitrogen Pesticides in Vegetables and Fruits. *Journal of the food hygienic society of japan* 36: 607-612.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Systematic determination of organophosphorus, pyrethroid and organonitrogen pesticides in vegetables and fruits by GC was developed. Pesticides were extracted from samples using acetone, and re-extracted into hexane.

Organophosphorus pesticides in the extract were directly determined by FPD-GC. For determination of pyrethroid (ECD-GC) and organonitrogen (NPD-GC) pesticides, the extract was purified by Florisil column chromatography using 30% ethyl acetate-hexane. The detection limits were 0.005-0.02 ppm for pesticides. Organophosphorus, pyrethroid and organonitrogen pesticides were spiked at 0.1 ppm, 0.2 ppm and 0.2 ppm, respectively. Except for dimethoate, ethiofencarb and lenacil, recoveries of pesticides were over 60%.

1269. Takashima, Shiro, Kuchumov, Askar R., and Vinogradov, Serge N. (1999). The apparently symmetrical hexagonal bilayer hemoglobin from Lumbricus terrestris has a large dipole moment. *Biophysical Chemistry* 77: 27-35.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The giant ~3.6 MDa hexagonal bilayer hemoglobin (HBL Hb) from Lumbricus terrestris consists of 12 213-kDa dodecamers of four globin chains ([b+a+c]3[d]3) tethered to a central scaffold of ~36 non-globin, linker subunits L1-L4 (24-32 kDa). Three-dimensional reconstructions obtained by electron cryomicroscopy showed it to have a D6 point-group symmetry, with the two layers rotated ~16[degree sign] relative to each other. Measurement of the dielectric constants of the Hb and the dodecamer over the frequency range 5-100 kHz indicated relaxation frequencies occurring at 20-40 and 300 kHz, respectively, substantially lower than the 700-800 kHz in HbA. The dipole moments calculated using Oncley's equation were 17[punctuation space]300+/-2300 D and 1400 D for the Hb and dodecamer, respectively. The approximately threefold higher dipole moment of the dodecamer relative to HbA is consistent with an asymmetric shape in solution suggested by small-angle X-ray scattering. Although a two-term Debye equation and a prolate ellipsoid of revolution model provided a good fit to the experimental dielectric dispersion of the dodecamer, a three-term Debye equation based on an oblate ellipsoid of revolution model was required to fit the asymmetric dielectric dispersion curve of the Hb: the required additional term may represent either an induced dipole moment or a substructure which rotates independently of the main permanent dipole component of the Hb. The D6 point-group symmetry implies that the dipole moments of the dodecamers cancel out. Thus, in addition to a possible contribution from fluctuations of the proton distribution, the large dipole moment of the Hb may be due to an asymmetric distribution of the heterogeneous linker subunits. Patent Application Country: Application: US
Priority Application Country: IL
Priority Application Number: 2002-152486
Priority Application Date: 20021025 Safe and effective foamable compns. for treating a subject infested with a parasitic arthropod or for preventing infestation include a first insecticide; >=1 org. carrier selected from a hydrophobic carrier, a polar solvent, an emollient and mixts. thereof at 2-50% by wt.; .apprx.0.1-5% by wt. of a surface-active agent; .apprx.0.01-5% by wt. of >=1 polymeric agent selected from a bioadhesive agent, a gelling agent, a film-forming agent and a phase change agent; and a liquefied or compressed gas propellant at .apprx.3-25% by wt. of the total compn. The org. carrier may comprise a second insecticide and(or) a potent solvent. Thus, a foamable insecticide compn. contg. permethrin (1 %), star anise oil (2.00% wt./wt. as second insecticide) and diisopropyl adipate and di-Me isosorbide as potent solvents was safe and effective in the treatment of head lice (Pediculosis capitis) in pediatric patients. [on SciFinder (R)] foam/ insecticide/ ectoparasiticide/ louse

1272. Tanabe, Akiko, Mitobe, Hideko, Kawata, Kuniaki, Sakai, Masaaki, and Yasuhara, Akio (2000). New monitoring system for ninety pesticides and related compounds in river water by solid-phase extraction with determination by gas chromatography/mass spectrometry. *Journal of AOAC International* 83: 61-77.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Database: CAPLUS
Accession Number: AN 2000:99561

Pesticides (18 fungicides, 30 insecticides, 42 herbicides) were extd. with a solid-phase, styrene-divinylbenzene copolymer; eluted with acetone, hexane, and Et acetate; and detd. by gas chromatog.-mass spectrometry. Overall recovery was 72-118%. Limits of detection were 0.01-0.1 mg/L. This system detd. most pesticides used in Japan and was successfully used for practical monitoring of water polluted by pesticides and related compds. Chem Codes: Chemical of Concern: PSM Rejection Code: IN VITRO.

Lanthanides such as La3+ and Gd3+ are well known to have large effects on the function of membrane proteins such as mechanosensitive ionic channels and voltage-gated sodium channels, and also on the structure of phospholipid membranes. In this report, we have investigated effects of La3+ and Gd3+ on the shape of giant unilamellar vesicle (GUV) of dioleoylphosphatidylcholine (DOPC-GUV) and GUV of DOPC/cholesterol by the phase-contrast microscopy. The addition of 10-100 [mu]M La3+ (or Gd3+) through a 10-[mu]m diameter micropipette near the DOPC-GUV (or DOPC/cholesterol-GUV) triggered several kinds of shape changes. We have found that a very low concentration (10 [mu]M) of La3+ (or Gd3+) induced a shape change of GUV such as the discocyte via stomatocyte to inside budded shape transformation, the two-spheres connected by a neck to prolate transformation, and the pearl on a string to cylinder (or tube) transformation. To understand the effect of these lanthanides on the shape of the GUV, we have also investigated phase transitions of 30 [mu]M dipalmitoylphosphatidylcholine-multilamellar vesicle (DPPC-MLV) by the ultra-sensitive differential scanning calorimetry (DSC). The chain-melting phase transition temperature and the L[beta]' to P[beta]' phase transition temperature of DPPC-MLV increased with an increase in La3+ concentration. This result indicates that the lateral compression pressure of the membrane increases with an increase in La3+ concentration. Thereby, the interaction of La3+ (or Gd3+) on the external monolayer membrane of the GUV induces a decrease in its area (Aex), whereas the area of the internal monolayer membrane (Ain) keeps constant. Therefore, the shape changes of the GUV induced by these lanthanides can be explained reasonably by the decrease in the area difference between two monolayers ([Delta]A=Aex-Ain). Citations: 33) Leo, A; Handbook of Chemical Property Estimation Methods 1982, 1 A fragment const. model for prediction of KOC was developed and evaluated with a diverse database of 592 chems. belonging to 17 classes. The range of exptl. KOC covered 7.65 log-units. The 592 chems. were randomly divided into a training set and a testing set for model development and validation. A general model was then established using the entire database having 74 fragment consts. and 24 structural factors. Statistically, the regression model accounted for as much as 96.96% of the variation in the measured log KOC. The mean residual between the exptl. and predicted KOC values was 0.366 log-units. In >74% of the chems. studied the residual values were <0.5 log-units. The robustness of the regression model, with respect to either specific individual chems. or particular compd. classes, was evaluated through use of jackknife tests. The results confirmed the ability of the fragment model to predict KOC for a wide variety of untested chems. 1276. Tao, Yizhi, Olson, Norman H., Xu, Wei, Anderson, Dwight L., Rossmann, Michael G., and Baker, Timothy S. (1998). Assembly of a Tailed Bacterial Virus and Its Genome Release Studied in Three Dimensions. *Cell* 95: 431-437.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

We present the first three-dimensional reconstruction of a prolate, tailed phage, and its empty prohead precursor by cryo-electron microscopy. The head-tail connector, the central component of the DNA packaging machine, is visualized for the first time in situ within the Bacillus subtilis dsDNA phage [phi]29. The connector, with 12- or 13-fold symmetry, appears to fit loosely into a pentameric vertex of the head, a symmetry mismatch that may be required to rotate the connector to package DNA. The prolate head of [phi]29 has 10 hexameric units in its cylindrical equatorial region, and 11 pentameric and 20 hexameric units comprise icosahedral end-caps with T=3 quasi-symmetry. Reconstruction of an emptied phage particle shows that the connector and neck/tail assembly undergo significant conformational changes upon ejection of DNA.

ABSTRACT: TD3: In December 1990, the Laboratory of Radiation Research (LSO) of the National Institute of Public Health and Environmental Protection (RIVM) set up an HVS sampling station at Bilthoven. This report is intended to describe the development of the HVS system, therefore the discussion of both equipment and analysis is emphasized. A general description of the HVS method is given in the first part of Chapter 2. In subsections, the methods of air-sampling, sample preparation and analysis are discussed. Detection limits, accuracy, and quality assurance are described in the last three sections of Chapter 2. The results of radionuclides measurements in air in 1991 and 1992 and those of additional investigations on the effect of sample pretreatment are included in Chapter 3. Chapter 4 rounds of the report with the conclusions. Detailed tables showing results over 1991 and 1992 are given in the Appendix. Errata sheet inserted. Summary in Dutch.

Batsch) fruit; postharvest, post hydrocooled, and post brushed fruit were assessed for levels of several pesticides. The packing house process reduced pesticide residue levels on fresh peaches to levels that were generally below detection limits of our assays in 1998. Carbaryl and captan residues from field packed fruit were 32.2* and 21.9*, resp., of that found in the peel of fruit processed in the packing house in 1998. Carbaryl levels were not reduced by hydrocooling but postharvest brushing reduced pesticide residues up to 94% in fruit peel. Across processing operations and cultivars assessed in 1999, hydrocooling, hydrocooling plus brushing, and brushing alone removed 37%, 62%, and 53%, resp., of the encapsulated methyl parathion residues from fruit peel. Hydrocooling had the greatest impact on phosmet removal from peel, reducing levels by 72.5 %. After hydrocooling, phosmet was, 5.7* following brushing in one-half of the subsequent samples. This increase occurred at all three farms, suggesting that periodic cleaning of brushes may be necessary to prevent later contamination of peach peel with pesticides. In the only example in which propiconazole residue remained on peaches at, picking, it was removed most effectively (69 %) by the brushing operation. Nearly 31 % of the propiconazole was removed in the hydrocooler. The packing process before shipment to retail outlets was generally effective in the removal of pesticides that may be present on peel at the time of harvest. Assessment of pesticide residue levels in peach flesh was uniformly below the levels of detection in our assays, suggesting that the classes of pesticide analyzed in peaches were not transepidermal. Abstract: Pollen of Proustia (10 specimens examined) and Lophopappus (12 specimens examined) (Asteraceae, Mutisieae) are described as part of an analysis of the classification of these genera. Their exine structure is determined and compared with structures found in other genera of Mutisieae (25 specimens examined and data of other authors), in order to clarify the subtribal position of Proustia and Lophopappus. Pollen of Proustia and Lophopappus have the following characters in common: Grains radially symmetrical and isopolar; tricolporate, long colpi with a microgranulate membrane, endoaperture lalongate with acute or bifurcate equatorial ends; subprolate or prolate-spheroidal; elliptic or spheroidal; polar caps conspicuous or not so distinctive, and exine microechinate. Two types of sexine structure are observed: (1) Trixis type, with two columellate ramified sublayers, the inner sublayer thicker than the outer one (found in Lophopappus berberidifolius, L. tarapacanus, Proustia cuneifolia var. cuneifolia, P. cuneifolia var. mendocina, P. cuneifolia var. mollis, P. ilicifolia var. baccharoides, and P. pyrifolia); and (2) Proustia type, with two equally thick sublayers of ramified columella (found in Lophopappus blakei, L. cuneatus, and L. foliosus). Proustia ilicifolia var. ilicifolia and Lophopappus peruvianus have both types of sexine structure. Pollen analysis of other genera of Mutisieae subtribes Nassauviinae, Mutisiinae and Gochnatiinae demonstrate two new exine types: (1) Ainsliaea type, with two sublayers poorly distinguishable, the exine appearing compact, the outer surface microechinate; and (2) Wunderlichia type, with two well-differentiated sublayers, the outer surface echinate, the spines with apical channels. The results show that: (1) Proustia and Lophopappus cannot be differentiated from each other by pollen characters; (2) the genera of subtribe Nassauviinae can be differentiated from the other two subtribes by having sexine sublayers with similar structure; (3) Proustia and Lophopappus have the pollen exine structural types that are typical of pollen of subtribe Nassauviinae; (4) subtribes Gochnatiinae and Mutisiinae are characterized by having sexine sublayers with different structures; but (5) those two subtribes cannot be differentiated based on pollen characters. 1283. Thakur, S. N. and Upadhya, K. N. (1969). A high resolution investigation of the near ultraviolet absorption spectrum of p-fluorochlorobenzene. *Journal of Molecular Structure* 4: 459-467.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The intense b ands in the near ultraviolet absorption spectrum of p-fluoro-chlorobenzene show regular rotational features under high resolution. Band contour analysis confirms the electronic transition to be 1B2 <-- 1A1. The rotational lines have been interpreted by a prolate symmetric rotor model for the molecule. The observed rotational constants indicate that the size of the phenyl ring increases on electronic excitation. http://www.sciencedirect.com/science/article/B6TGS-44BMVKR-1F/2/f4d0e53f26fc2dc519cb0db6374145c3

Abstract: Tree-based intercropping is considered an excellent farming system and can contribute much to our understanding of sustainable agriculture practices. Our current research goals are to address and quantify the numerous biophysical interactions that occur at the tree-crop interface in order to enhance our understanding of the ecology of tree-based intercropping (a form of agroforestry). In 1987, the University of Guelph established a large field experiment on 30 ha of prime agricultural land in Wellington county southern Ontario, Canada to investigate various aspects of intercropping trees with agricultural crops. A variety of spacing, crop compatibility and tree growth, and survival experiments were initiated at that time, utilizing 10 tree species within the genera Picea, Thuja, Pinus, Juglans, Quercus, Fraxinus, Acer, and Populus. Two between row-spacings (12.5 m or 15 m) and two within row-spacings (3 m, or 6 m) were utilized in conjunction with all possible combinations of three agricultural crops (soybean, corn, and either winter wheat or barley). Investigations over the last decade have documented several complementary biophysical interactions. Nitrogen (N) transfer from fall-shed leaves to adjacent crops with enhanced soil nitrification as the proposed mechanism was estimated to be 5 kg N ha⁻¹. Soil organic carbon (C) adjacent to tree rows has increased by over 1%, largely as a result of tree litterfall inputs and fine root turnover. It is estimated that intercropping has reduced nitrate loading to adjacent waterways by 50%, a hypothesized function of deep percolate interception by tree roots. We have also noticed increased bird diversity and usage within the intercropped area as compared to mono-cropped adjacent agricultural areas, and have recorded increases in small mammal populations. Earthworm distribution and abundance was also found to be higher closer to the tree rows when compared to earthworm numbers in the crop alleys. We speculate that these are indicative of major changes in the flow of energy within the trophic structure identified with intercropping systems. In light of climate change mitigation processes, C

sequestration and NO<inf>2</inf> reduction potentials in tree-based intercropping systems were studied and compared to conventional agricultural systems. The results suggest that sequestration of C was 5 times more in the former system than in the latter. Competitive interactions between trees and crops for nutrients, moisture and light were also studied. The tangible benefits that are derived from properly designed and managed tree-based intercropping systems place this land management option above conventional agriculture in terms of long-term productivity and sustainability. Abstract: The 'ellipsoidal distribution', in which angles are assumed to be distributed parallel to the surface of an oblate or prolate ellipsoid, has been widely used to describe the leaf angle

distribution (LAD) of plant canopies. This ellipsoidal function is constrained to show a probability density of zero at an inclination angle of zero; however, actual LADs commonly show a peak probability density at zero, a pattern consistent with functional models of plant leaf display. A 'rotated ellipsoidal distribution' is described here, which geometrically corresponds to an ellipsoid in which small surface elements are rotated normal to the surface. Empirical LADs from canopy and understory species in an old-growth coniferous forest were used to compare the two models. In every case the rotated ellipsoidal function provided a better description of empirical data than did the non-rotated function, while retaining only a single parameter. The ratio of G-statistics for goodness of fit for the two functions ranged from 1.03 to 3.88. The improved fit is due to the fact that the rotated function always shows a probability density greater than zero at inclination angles of zero, can show a mode at zero, and more accurately characterizes the overall shape of empirical distributions. Abstract: Field peas (Pisum sativum L.) were grown in sequence with winter wheat (Triticum aestivum L.) or spring barley (Hordeum vulgare L.) in large outdoor lysimeters. The pea crop was harvested either in a green immature state or at physiological maturity and residues returned to the lysimeters after pea harvest. After harvest of the pea crop in 1993, pea crop residues (pods and straw) were replaced with corresponding amounts of ¹⁵N-labelled pea residues grown in an adjacent field plot. Reference lysimeters grew sequences of cereals (spring barley/spring barley and spring barley/winter wheat) with the straw removed. Leaching and crop offtake of ¹⁵N and total N were measured for the following two years. These treatments were tested on two soils: a coarse sand and a sandy loam. Nitrate concentrations were greatest in percolate from lysimeters with immature peas. Peas harvested at maturity also raised the nitrate concentrations above those recorded for continuous cereal growing. The cumulative nitrate loss was 9-12gNO<inf>3</inf>-Nm⁻² after immature peas and 5-7 g NO<inf>3</inf>Nm<inf>-2</inf> after mature peas. Autumn sown winter wheat did not significantly reduce leaching losses after field peas compared with spring sown barley, ¹⁵N derived from above-ground pea residues accounted for 18-25% of the total nitrate leaching losses after immature peas and 12-17% after mature peas. When compared with leaching losses from the cereals, the extra leaching loss of N from roots and rhizodeposits of mature peas were estimated to be similar to losses of ¹⁵N from the above-ground pea residues. Only winter wheat yield on the coarse sand was increased by a previous crop of peas compared to wheat following barley. Differences between barley grown after peas and after barley were not statistically significant. ¹⁵N lost by leaching in the first winter after incorporation accounted for 11-19% of ¹⁵N applied in immature pea residues and

10-15% of ¹⁵N in mature residues. Another 2-5% were lost in the second winter. The ¹⁵N recovery in the two crops succeeding the peas was 3-6% in the first crop and 1-3% in the second crop. The winter wheat did not significantly improve the utilization of ¹⁵N from the pea residues compared with spring barley.

Abstract: Small angle X-ray scattering in solution was performed on seed-storage proteins from wheat. Three different groups of gliadins (alpha -, gamma - and omega -) and a high molecular weight (HMW) subunit of glutenin (1Bx20) were studied to determine molecular size parameters. All the gliadins could be modelled as prolate ellipsoids with extended conformations. The HMW subunit existed as a highly extended rod-like particle in solution with a length of about 69 nm and a diameter of about 6.4 nm. Specific aggregation effects were observed which may reflect mechanisms of self-assembly that contribute to the unique viscoelastic properties of wheat dough.

Chem Codes: Chemical of Concern: PSM Rejection Code: NON-ENGLISH.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Covering a crop of Chinese cabbage with fibrelike nets of plastic makes it possible to protect the plants from attacks by insects such as the cabbage root fly. By this technique the crop can be grown without the application of insecticides. Several new plastic materials made of polypropylene used in growth promotion of vegetable crops are suitable for this purpose. Obviously the net material needs to be intact during the whole covering period, which might be up until a fortnight before harvest. Accidental perforation requires replacement of the net or implementation of a spraying programme with insecticides.

1290. Tice, Colin M (2002). Selecting the right compounds for screening: use of surface-area parameters. *Pest Management Science* 58: 219-233.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Copyright: Copyright (C) 2007 ACS on SciFinder (R))
Database: CAPLUS
Accession Number: AN 2002:210355
Chemical Abstracts Number: CAN 136:381730
Section Code: 5-4
Section Title: Agrochemical Bioregulators
Document Type: Journal
Language: written in English.
Index Terms: Surface area (mol.; use of surface-area parameters for agrochem. screening of

herbicides and insecticides); Herbicides; Insecticides; Polar effect (use of surface-area parameters for agrochem. screening of herbicides and insecticides)
CAS Registry Numbers: 162320-67-4 (Flufenzine) Role: AGR (Agricultural use), PRP (Properties), BIOL (Biological study), USES (Uses) (Flufenzine; use of surface-area parameters for agrochem. screening of herbicides and insecticides); 50-29-3 (DDT); 52-68-6 (Trichlorfon); 54-11-5 (Nicotine); 55-38-9 (Fenthion); 56-38-2 (Parathion); 57-39-6 (Metepa); 58-89-9 (Lindane); 60-51-5 (Dimethoate); 61-82-5 (Amitrole); 62-73-7 (Dichlorvos); 63-25-2 (Carbaryl); 70-43-9 (Barthrin); 72-43-5 (Methoxychlor); 72-54-8 (TDE); 72-56-0 (Ethylan); 76-03-9 (TCA); 76-44-8 (Heptachlor); 78-57-9 (Menazon); 80-33-1 (Chlorfenson); 83-79-4 (Rotenone); 86-50-0 (Azinphos-methyl); 93-65-2 (Mecoprop); 93-71-0 (CDAA); 94-74-6 (MCPA); 94-75-7 (2,4-D); 94-81-5 (MCPB); 94-82-6 (2,4-DB); 97-17-6 (Dichlofenthion); 101-42-8 (Fenuron); 107-49-3 (TEPP); 114-26-1 (Propoxur); 115-26-4 (Dimefox); 115-32-2 (Dicofol); 115-90-2 (Fensulfothion); 116-06-3 (Aldicarb); 116-29-0 (Tetradifon); 119-12-0 (Pyridaphenthion); 120-36-5 (Dichlorprop); 121-20-0 (Cinerin II); 121-21-1 (Pyrethrin I); 121-75-5 (Malathion); 122-10-1 (Bomyl); 122-14-5 (Fenitrothion); 122-34-9 (Simazine); 126-22-7 (Butonate); 133-90-4 (Chloramben); 139-40-2 (Propazine); 141-66-2 (Dicrotophos); 143-50-0 (Chlordecone); 144-41-2 (Morphothion); 150-68-5 (Monuron); 152-16-9 (Schradan); 297-78-9 (Isobenzan); 297-97-2 (Thionazin); 298-00-0 (Parathion-methyl); 298-02-2 (Phorate); 298-04-4 (Disulfoton); 299-84-3 (Fenchlorphos); 300-76-5 (Dibrom); 301-12-2 (Oxydemeton-methyl); 311-45-5 (Paraoxon); 315-18-4 (Mexacarbate); 327-98-0 (Trichloronate); 333-41-5 (Diazinon); 470-90-6 (Chlorfenvinfos); 510-15-6 (Chlorobenzilate); 534-52-1 (DNOC); 545-55-1 (TEPA); 555-37-3 (Neburon); 563-12-2 (Ethion); 584-79-2 (Allethrin); 640-15-3 (Thiometon); 644-64-4 (Dimetilan); 709-98-8 (Propanil); 732-11-6 (Phosmet); 741-58-2 (Bensulide); 759-94-4 (EPTC); 786-19-6 (Carbophenothion); 834-12-8 (Ametryne); 841-06-5 (Methoprotryne); 886-50-0; 919-86-8 (Demeton-S-methyl); 944-22-9 (Fonofos); 947-02-4 (Phosfolan); 950-10-7; 950-37-8 (Methidation); 957-51-7 (Diphenamid); 1031-47-6 (Triamiphos); 1071-83-6 (Glyphosate); 1113-02-6 (Omethoate); 1114-71-2 (Pebulate); 1129-41-5 (Metolcarb); 1134-23-2 (Cycloate); 1172-63-0 (Jasmolin II); 1194-65-6 (Dichlobenil); 1420-07-1 (Dinoterb); 1563-66-2 (Carbofuran); 1582-09-8 (Trifluralin); 1610-18-0 (Prometon); 1646-88-4 (Aldoxycarb); 1689-83-4 (Ioxynil); 1689-84-5 (Bromoxynil); 1698-60-8 (Chloridazon); 1702-17-6 (Clopyralid); 1836-75-5 (Nitrofen); 1861-32-1 (Dacthal); 1861-40-1 (Benfluralin); 1912-24-9 (Atrazine); 1912-26-1 (Trietazine); 1918-00-9 (Dicamba); 1918-11-2 (Terbucarb); 1918-16-7 (Propachlor); 1982-47-4 (Chloroxuron); 1982-49-6 (Siduron); 2008-41-5 (Butylate); 2032-65-7 (Methiocarb); 2104-64-5 (EPN); 2104-96-3 (Bromophos); 2164-08-1 (Lenacil); 2164-17-2 (Fluometuron); 2212-67-1 (Molinate); 2227-17-0 (Dienochlor); 2275-18-5 (Prothoate); 2275-23-2 (Vamidothion); 2303-16-4 (Diallate); 2303-17-5 (Triallate); 2310-17-0 (Phosalone); 2312-35-8 (Propargite); 2385-85-5 (Mirex); 2425-10-7 (Xylylcarb); 2439-01-2 (Quinomethionate); 2463-84-5 (Dicapthon); 2497-07-6 (Oxydisulfoton); 2540-82-1 (Formothion); 2595-54-2 (Mecarbam); 2597-03-7 (Phenthoate); 2631-37-0 (Promecarb); 2631-40-5 (Isoprocarb); 2636-26-2 (Cyanophos); 2655-14-3 (XMC); 2655-19-8 (Butacarb); 2674-91-1 (Oxydeprofos); 2921-88-2 (Chlorpyriphos); 2941-55-1 (Ethiolate); 3060-89-7 (Metobromuron); 3244-90-4 (Aspon); 3309-87-3 (DMCP); 3337-71-1 (Asulam); 3689-24-5 (Sulfotep); 3766-81-2 (Fenobucarb); 3792-59-4 (EPBP); 3811-49-2 (Dioxabenzofos); 3813-05-6 (Benazolin); 3942-54-9 (CPMC); 4151-50-2 (Sulfluramid); 4824-78-6 (Bromophos-ethyl); 4849-32-5 (Karbutilate); 5598-13-0; 5827-05-4 (IPSP); 5902-51-2 (Terbacil); 5915-41-3 (Terbuthylazine); 6164-98-3 (Chlordimeform); 6923-22-4 (Monocrotophos); 6988-21-2 (Dioxacarb); 7287-19-6 (Prometryn); 7287-36-7 (Monalide); 7292-16-2 (Propaphos); 7696-12-0 (Tetramethrin); 7700-17-6 (Crotoxyphos); 7786-34-7 (Mevinphos); 8001-35-2 (Toxaphene); 10265-92-6 (Methamidophos); 10311-84-9 (Dialifor); 10453-86-8 (Resmethrin); 11141-17-6 (Azadirachtin); 12407-86-2 (Trimethacarb); 13067-93-1 (Cyanofenphos); 13071-79-9 (Terbufos); 13171-21-6 (Phosphamidon); 13181-17-4 (Bromofenoxim); 13194-48-4 (Ethoprophos); 13360-45-7 (Chlorbromuron); 13593-03-8 (Quinalphos); 13684-56-5 (Desmedipham); 13684-63-4 (Phenmedipham); 14816-18-3 (Phoxim); 14816-20-7 (Chlorphoxim); 15263-53-3 (Cartap); 15299-99-7 (Napropamide); 15972-60-8 (Alachlor); 16752-77-5 (Methomyl); 17606-31-4 (Bensultap); 18181-70-9 (Iodofenphos); 18181-80-1 (Bromopropylate); 18854-01-8 (Isoxathion); 19044-88-3 (Oryzalin); 19937-59-8 (Metoxuron); 20354-26-1 (Methazole); 21548-32-3 (Fosthietan); 21609-90-5 (Leptophos); 21725-46-2 (Cyanazine); 22224-92-6 (Fenamiphos); 22248-79-9 (Tetrachlorvinfos); 22259-30-9

Citations: 38) Reynolds, C; J Chem Inf Comput Sci 1998, 38, 305 Polar surface area, total surface area and percentage surface area have been calcd. from three-dimensional structures of 88 post-emergence herbicides, 93 pre-emergence herbicides and 237 insecticides. Preferred ranges of values of these parameters were identified. Since the compds. in the training sets are used on a wide variety of species and target sites with various application modes, the parameter ranges are necessarily broad. The utility of the surface-area parameter ranges in selection of compds. for agrochem. screening was compared with the use of ranges of the Lipinski Rule of 5 parameters: mol. mass, calcd. log P, no. of hydrogen-bond donors and no. of hydrogen-bond acceptors. The more computationally intensive surface-area parameters did not offer any obvious advantage over the Lipinski Rule of 5 parameters. [on SciFinder (R)] 1526-498X surface/ area/ parameter/

Chem Codes: Chemical of Concern: PSM Rejection Code: NON-ENGLISH.

ABSTRACT: PESTAB. The toxicity of different pesticides, such as parathion, malathion, lindane, endrin, diazinon, phenylmercury acetate, DDT, and metasystox to Trichogramma evanescens Westw. and Tr. embryophagum Htg. was studied to determine the optimal conditions for combined application of pesticides, biological preparations, and Trichogramma in pest control. Trichogramma was found to be highly susceptible to pesticides even in concentrations substantially below those commonly used in practice. Therefore, integrated pest control systems, including Trichogramma should not include broad-spectrum insecticides with high initial and residual toxicity, such as carbaryl, phthalophos, and rogor. Selective preparations of those with short-term toxic effect, such as phosalone and trichlorfon should be used. Trichogramma was found to be susceptible to entobacterin, both in pure form and in mixtures with small amounts of trichlorfon, carbaryl, and rogor (dimethoate). The findings indicate that insecticides and entobacterin can not be used simultaneousy with Trichogramma.

Citations: 33) Faucon, J; Chemosphere 2001, 44, 407 A topol. parameter is defined as an integer value of a given local or global invariant of a mol. graph. We examd. three types of local graph invariants, the vertex degrees (0EC), the extended connectivity of first order (1EC), and the nos. of paths of length two (P2), as elementary invariants for construction of quant. structure-activity relationships (QSAR). We also examd. combined invariants, obtained by multiplying one of these three elementary types with another (i.e., [0EC.1EC], [0EC.P2], and [1EC.P2]), as graph invariants. Finally, global invariants were used in the QSAR analyses, codifying the presence and nature of cycles in the mol. structures under consideration. We used the correlation wts. of these invariants to obtain optimal descriptors. These descriptors have been used in one-variable models to predict toxicity toward Daphnia magna for a set of pesticides. Statistical characteristics of the best model, based on the correlation wt. of local topol. parameters (the [0EC.P2]) together with the global topol. parameters, are the following: n = 220, r2 = 0.7822, s = 0.849, F = 783 (training set); n = 42, r2 = 0.7388, s = 0.941, F = 113 (test set). The role of these topol. parameters is discussed. [on SciFinder (R)] 0968-0896 QSAR/ model/ Daphnia/ toxicity/ pesticide/ mol/ topol

CAS Registry Numbers: 115-32-2 (Dicofol); 116-29-0 (Tetradifon); 121-75-5 (Malathion); 122-14-5 (Fenitrothion); 133-07-3 (Folpet); 298-00-0 (Parathion-methyl); 333-41-5 (Diazinon); 470-90-6 (Chlorfenvinphos); 563-12-2 (Ethion); 732-11-6 (Phosmet); 786-19-6 (Carbophenothion); 950-37-8 (Methidathion); 959-98-8; 2425-06-1 (Captafol); 2921-88-2 (Chlorpyriphos); 33213-65-9 Role: ANT (Analyte), BOC (Biological occurrence), BSU (Biological study, unclassified), POL (Pollutant), ANST (Analytical study), BIOL (Biological study), OCCU (Occurrence) (detn. of pesticide residues in fruit and vegetables by matrix solid phase dispersion and different gas chromatog. element-selective detectors) A comparison between different element selective detectors for the detn. of organophosphorus and organochlorine pesticide residues, from fruit and vegetables, was performed by capillary GC with electron capture detector (ECD), nitrogen

phosphorus detector (NPD), flame photometric detector (FPD) in the sulfur and phosphorus modes, and mass spectrometry detector (MSD) in selected ion monitoring (SIM) mode. Pesticides were extd. from the different foodstuffs by Matrix Solid Phase Dispersion (MSPD). Recoveries of 41-108% with relative std. deviation of 2-14% in the concn. range 0.5-10 mg L-1 were obtained in oranges, lemons, grapefruit, pears, plums, lettuce, and tomatoes. The results demonstrated that the exts. of all the samples can be analyzed by the detectors used since no interfering co-extd. compds. were detected. Index Terms: Insecticides (extn.-gas chromatog. detn. of insecticides in oranges); Orange (multiresidue extn. method based on matrix solid-phase dispersion and gas chromatog. detn. of insecticides in); Food contamination (pesticides in oranges from Valencia central market in Spain); Extraction (liq.-solid, matrix solid-phase dispersion extn. procedure for multiresidue pesticide anal. in oranges)
CAS Registry Numbers: 86-50-0 (Methyl-azinphos); 115-32-2 (Dicofol); 116-29-0 (Tetradifon); 121-75-5 (Malathion); 122-14-5 (Fenitrothion); 133-07-3 (Folpet); 298-00-0 (Methyl-parathion); 309-00-2 (Aldrin); 333-41-5 (Diazinon); 470-90-6 (Chlorfenvinphos); 563-12-2 (Ethion); 732-11-6 (Phosmet); 786-19-6 (Carbophenothion); 950-37-8 (Methidathion); 959-98-8 (a-Endosulfan); 2425-06-1 (Captafol); 2921-88-2 (Chlorpyriphos); 33213-65-9 (b-Endosulfan) Role: ANT (Analyte), POL (Pollutant), ANST (Analytical study), OCCU (Occurrence) (extn.-gas chromatog. detn. of insecticides in oranges) A multiresidue extn. method based on matrix solid-phase dispersion (MSPD) is optimized for the extn. and gas chromatog. screening of eighteen insecticides (aldrin, carbophenothion, captafol, chlorpyriphos, chlorfenvinphos, diazinon, dicofol, a-endosulfan, b-endosulfan, ethion, fenitrothion, folpet, methidathion, malathion, methyl-azinphos, methyl-parathion, phosmet, and tetradifon) from oranges. After optimization of different parameters, such as type of solid phase used and the amt. of solid phase or eluent, recoveries ranged from 67 to 102% with relative std. deviations ranging from 2 to 10%. The limits of detection, calcd. as 3 times the baseline noise, ranged from 2 to 171 mg/kg. These limits of detection were about 10 times lower than the max. residue levels established by the European Community. Compared with classical methods, the described procedure is simple, less labor intensive and does not require prepn. and maintenance of equipment. Troublesome emulsions, such as those frequently obsd. in liq.-liq. partitioning, did not occur. [on SciFinder (R)] 0021-9673 insecticide/ detn/ orange/ extn/ chromatog;/ gas/ chromatog/ insecticide

The organophosphorus pesticides carbophenothion, chlorpyriphos, chlorfenvinphos, diazinon, ethion, fenitrothion, malathion, methidation, methylparathion, phosmet, quinalphos, and tetradifon were simultaneously extd. by matrix solid-phase dispersion and detd. by gas chromatog.-mass spectrometry using selected ion monitoring mode. A total of 32.25% contained pesticide residues and 6.9% exceeded the European Union Maximum Residue Levels (MRLs). The pesticides found in the samples with residues above MRLs were carbophenothion, ethion, methidathion, and methyl parathion. Lower level residues of these and the other pesticides studied (except diazinon) were frequently found. The estd. daily intake of the 12 organophosphorus pesticide residues during the studied period was 4.87 * 10-4 mg/kg body wt./day. This value is

lower than the provisional tolerance dairy intakes proposed by the Food and Agriculture Organization and the World Health Organization. [on SciFinder (R)] 1060-3271 citrus/ fruit/ organophosphorus/ pesticide/ Spain

Patent Application Country: Application: WO
Priority Application Country: US
Priority Application Number: 2001-1664
Priority Application Date: 20011023 The invention relates to methods of increasing the relative concn. of a target mol. in a gas stream, so that it can be more easily detected by a semiconducting metal oxide based sensor. In a first step of one method, a gas stream is passed through an adsorbent. The gas stream contains mols. of the target mol. in a mixt. contg. mols. of at least one non-target mol. Both the target and non-target mols. are adsorbed on the adsorbent. In a second step, another gas stream contg. mols. of a chem. displacer is passed through the adsorbent. The mols. of the chem. displacer adsorb on the adsorbent to selectively displace the target mols. from the adsorbent while leaving the non-target mols. adsorbed. The chem. displacement causes the displaced target mols. to enter the gas stream. The gas stream can then be passed through a semiconducting metal oxide based sensor to detect the target mols. Alternatively, the adsorbed chem. displacer displaces the non-target mols. while leaving the target mols. adsorbed on the adsorbent surface. In either case, a sepn. of the target and non-target mols. is achieved. In another method, an adsorbent is pretreated with a chem. displacer so that chem. displacer mols. are adsorbed on the adsorbent. A gas stream is passed through the adsorbent, the gas stream contg. target mols. mixed non-target mols. The target mols. adsorb on the adsorbent while the nontarget mols. do not adsorb and instead remain in the gas stream. The chem. displacer mols. are selectively adsorbed relative to the non-target mols. to prevent their adsorption on the adsorbent. Alternatively, the chem. displacer can be selectively adsorbed relative to the target mols., so that the non-target mols. adsorb on the adsorbent while the target mols. do not adsorb and remain in the gas stream. 1301. Tripura, C., Sashidhar, B., and Podile, A. R. (Ethyl Methanesulfonate Mutagenesis-Enhanced Mineral Phosphate Solubilization by Groundnut-Associated Serratia Marcescens Gps-5. *Curr microbiol. 2007, feb; 54(2):79-84. [Current microbiology]: Curr Microbiol*.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

ABSTRACT: Twenty-three bacterial isolates were screened for their mineral phosphate-solubilizing (MPS) ability on Pikovskaya and National Botanical Research Institute's phosphate (NBRIP) agar. The majority of the isolates exhibited a strong ability to solubilize hydroxyapatite

in both solid and liquid media. The solubilization in liquid medium corresponded with a decrease in the pH of the medium. Serratia marcescens GPS-5, known for its biocontrol of late leaf spot in groundnut, emerged as the best solubilizer. S. marcescens GPS-5 was subjected to ethyl methanesulfonate (EMS) mutagenesis, and a total of 1700 mutants, resulting after 45 minutes of exposure, were screened on buffered NBRIP medium for alterations in MPS ability compared with that of the wild type. Seven mutants with increased (increased-MPS mutants) and 6 mutants with decreased (decreased-MPS mutants) MPS ability were isolated. All seven increased-MPS mutants were efficient at solubilizing phosphate in both solid and liquid NBRIP medium. Among the increased-MPS mutants, EMS XVIII Sm-35 showed the maximum (40%) increase in the amount of phosphate released in liquid medium compared with wild-type S. marcescens GPS-5, therefore, it would be a useful microbial inoculant in groundnut cultivation. EMS III Sm W, a nonpigmented mutant, showed the lowest solubilization of phosphate among the 6 decreased-MPS mutants.

The procedure involves a solid-phase extn. of the pesticides using 90 min C18 disks. Quant. detn. of the pesticides was carried out by capillary gas chromatog. with mass spectrometry detection in the SIM mode. Recovery at low mg/L levels was tested by extn. of spiked distd. water using either neg. (vacuum) or pos. pressure. The detection limit was 0.05 ng/L for trifluralin and 2 ng/L for the other compds.

based on a 10-L water sample. The method was compared with liq.-liq. extn. using the Goulden Large Sample Extractor. [on SciFinder (R)] 0009-5893 membrane/ extn/ disk/ pesticide/ detn/ water

ABSTRACT: PESTAB. Thin-layer chromatographic method for the determination of phthalophos (phosmet) and phosalone in water and fish is described. Following extraction with chloroform from water, and with n-hexane from fish, the extracts are purified on silica gel column, using petroleum ether: acetone (9:1) for elution. The pesticides are separated on Silufol or silica gel plate, using chloroform: benzene (2:1) as a solvent system. The plate is sprayed with bromophenol blue and then with 1% citric acid for visualization. The Rf value of phthalophos on Silufol plates

is 0.63 0.05, that of phosalone 0.83 0.05. On silica gel plate, the Rf values of phthalophos and phosalone are 0.4 0.05 and 0.6 0.05, respectively. To identify phosalone on Silufol plates, 4-aminoantipyrine should also be used for visualization. On Silufol plate, the sensitivity amounts to 0.025 mg/kg in fish, and 0.005 mg/l in water. The recovery rates are 80 5% in fish, and 90 7% in water.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Sod-podzolic and chernozemic soils treated with pesticides and herbicides were under study. Small arthropoda population was shown to decrease, especially in the cases of insecticides application; thus the number of small arthropoda may serve as integral index of soil chemical pollution for the biological monitoring.

The peach samples (n = 150) were collected preharvest (June-August 2001) from both conventional (n = 55) and ICM (n = 95) cultivations from the Pella and Imathia districts of Macedonia, Northern Greece. The residue levels of selected insecticides, fungicides and acaricides in peach samples were detd. by gas chromatog.-mass spectrometry following solid-phase extn. The concns. of all detected pesticides were lower than the max. residue limits (MRLs) in all peach samples grown with the ICM system ($p < 0.001$). However, chlorpyrifos residues at levels higher than the MRLs were detected in four peach samples (i.e. 7% of the total samples) grown by the conventional system. Comparing the results for both cultivation methods with the reported av. percentage (3.6%) of fruit samples with pesticide residues above the MRLs (European Union report for Greece in 2001), it was concluded that the initial implementation of the ICM in Greece was successful. The

present study indicates that ICM cultivation has a higher efficiency in terms of product safety and quality. Furthermore, the results suggest that the application of conventional cultivation requires continuous monitoring of various crop protection product levels. [on SciFinder (R)] 0265-203X

Citations: Taylor, J; Quality Assurance of Chemical Measurements 1987, 1 A procedure for the detn. of 13 organophosphate insecticides (OPs) in water, sediment and biota at low ppb levels is described. Samples were extd. with dichloromethane or acetone/hexane and cleaned up with micro-column silica gel chromatog. Measurements were made by dual capillary column gas chromatog. using both nitrogen-phosphorus (NPD) and electron capture (ECD) detection. Recoveries from fortified water samples ranged from 76% to 102% for all sample types. Practical detection limits ranged between 0.003 and 0.029 mg/l in natural water samples, 0.0004-0.005 mg/g w.w. for sediments, and 0.001-0.005 mg/g w.w for biota using the NPD and ECD method. Losses in sediments were experienced when sulfur was removed. Precision and accuracy were not affected in sediment samples where sulfur was not removed. [on SciFinder (R)] 0045-6535

The stability of OP pesticides in samples fortified at 1-5 mg/Kg was studied. Samples were stored at 4 Deg for 1 wk and at -20 Deg for ?2 mo under both natural and acidic conditions. Initially a method was developed for the detn. of the 13 OP pesticides at sub mg/Kg levels. Sediment and the biota samples were extd. with hexane/acetone 80:20 followed by silica gel column fractionation. The measurements were made using a dual column GC equipped with a N-P detector and electron capture detector. Mean recoveries of OP pesticides from fortified sediment and biota samples in the 1-5 mg/Kg range were 76-91% for sediments and 78-96% for biota samples. Sediment samples stored at 4 Deg showed significant decompn. after 1 wk. Samples stored at -20 Deg were stable during the 1st month of storage, however, some decompn. was obsd. when the samples were analyzed after 2 mo. Similar results were obsd. for the biota

samples with the exception that diazinon and dibrom. After 1 mo of storage at -20 Deg, 57% of diazinon was recovered in natural samples, and none was recovered in any other stored samples. Dibrom was not recovered from samples stored at 4 Deg. [on SciFinder (R)] stability/ organophosphorus/ pesticide/ sediment/ biota

Abstract: We have already reported various pesticide contamination of water and fish (pale chub, ayu sweetfish and dark chub) from rivers flowing into Lake Biwa from April in 1988 to March in 1992. In this report, the same surveys were more extensively performed for twenty one pesticides (salithion, diazinon, IBP, tolclofosmethyl, chlorpyriphos, fenthion, malathion, fenitrothion, isofenphos, phenthoate, prothiophos, propaphos, methidathion, butamifos, isoprothiolane, edifenphos, EPN, pyridaphenthion, phosmet, benthiocarb and simetryne) from April in 1992 to March in 1993, and for nine pesticides (fenobucarb, carbofuran, simazine, chlorothalonil, pretilachlor, isoprothiolane, flutolanil, benthiocarb and simetryne) from April in 1993 to March in 1994.

Abstract: Pollen grains of six species in Thunbergia (subfamily Thunbergioideae), and of one species each in Staurogyne (subfamily Nelsonioideae) and Acanthus (subfamily Acanthoideae) in the Acanthaceae from China were examined under SEM. Pollen grains in Thunbergia are spheroidal, with the apertures being spiral and the exine ornamentation being psilate, granulate or rarely baculate. This pollen type is very special in this family and has been considered to represent a primitive condition. Pollen grains in Staurogyne are spheroidal, 3-colporate, with the exine ornamentation being psilate. Pollen grains in Acanthus are prolate, 3-colpate, with the exine ornamentation being finely reticulate or microperforate. Pollen morphological characteristics support the traditional placement of these three genera into three different subfamilies in the Acanthaceae.

CAS Registry Numbers: 53-57-6 Role: BIOL (Biological study) (enzyme requiring, from housefly in methylcarbamate insecticide metabolism); 10309-97-4 Role: BIOL (Biological study) (from Baygon reaction with enzyme of housefly); 50-29-3; 114-26-1; 309-00-2; 315-18-4; 671-04-5; 732-11-6; 2032-59-9; 2032-65-7 Role: BPR (Biological process), BSU (Biological study, unclassified), BIOL (Biological study), PROC (Process) (metabolism of, by enzyme of housefly)
Homogenates of the whole body of any of 6 housefly strains in the presence or absence of NADPH2 did not extensively metabolize 14C-labeled Baygon, but the abdomen homogenates of these insects were much more active than homogenates of the head, thorax, or whole body in the presence of NADPH2. This abdomen activity, almost specific for NADPH2, resided predominantly in the microsomal fraction. The addn. of homogenates of the head or thorax, individually or in combination, to the abdomen homogenates markedly reduced the activity of the

abdomen NADPH2-requiring enzyme system. The activity of the abdomen homogenate was greater for any of 3 carbamate-resistant strains than for any of 3 laboratory strains of the housefly. The enzyme activity was higher for adult files fed milk than it was for those fed sugar and water. Similar results were obtained for 9 other methylcarbamate insecticides. As detd. by tentative characterization of the methylcarbamate metabolites by autoradiography and thin-layer chromatog., aromatic hydroxylation occurred at either the 4- or 5-position of carbaryl, and O-dealkylation occurred with Baygon to yield 2-hydroxyphenol methylcarbamate. 25 references. The method requires only information on chem. structure of the compds. The thermodn. approach using the modified Watson equation was successfully applied to est. the vapor pressures of organophosphorus pesticides, including phosphorothionates, phosphorodithioates, phosphoramidothioates, phosphates, phosphorothiolates, and phosphorodithiolates. The optimization of the Watson method was found essential for correctly estg. the vapor pressures of organophosphorus compds., as were the adequate molar refraction of phosphorus atoms in the Eisenlohr correlation and the introduction of an empirical const. for the nitro group in Meissner's equation. The no. of possible hydrogen bond sites was found to improve the accuracy of estd. vapor pressures, esp. for pesticides possessing the P=O moiety. Our modified Watson equation

was used to successfully elucidate the vapor pressure of pesticides ranging from 10-5 to 101 Pa at 298 K and could be used to correctly predict the vapor pressures of other organophosphorus pesticides not utilized in the anal. A literature search learns that about 200 pesticides are gas chromatog. (GC) amenable, that quant. extn. procedures exist and these pesticides also give good recovery when gel permeation (GPC) is used for cleanup of exts. A strategy is discussed to develop a universal multipesticide method, esp. paying attention to plant material, using a universal very sensitive detection system, e.g. the ion trap detector. Exptl. data obtained with diverging matrixes are presented together with some thoughts on online GPC-GC combinations, using a temp. programmable injector in the GC system. 1318. Turiel, E. , Bordin, G., Rodr&Iacute, and Guez, A. R. (Trace Enrichment of (Fluoro)Quinolone Antibiotics in Surface Waters by Solid-Phase Extraction and Their Determination by Liquid Chromatography-Ultraviolet Detection. *J chromatogr a. 2003, aug 8; 1008(2):145-55. [Journal of chromatography. A]: J Chromatogr A.*
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS, FATE.

ABSTRACT: A new and simple analytical methodology for the simultaneous analysis of acidic and zwitterionic (fluoro)quinolones in surface waters at trace concentration level is presented. The method is based on the preconcentration of these analytes by a solid-phase extraction procedure and their subsequent quantification by liquid chromatography using ultraviolet detection. The breakthrough volumes of the selected (fluoro)quinolones in four different sorbents--C18, styrenedivinylbenzene (SDB), C18-cation-exchange and SDB-cation-exchange--have been evaluated and varied between 25 and 150 ml depending on the antibiotic and the sorbent used. An exhaustive study of the influence of sample pH on the preconcentration step has been carried out in order to find a suitable procedure for extraction of acidic and zwitterionic FQs in one single step. Under optimum conditions, it was possible to percolate up to 250 ml of water solution onto both C18 and SDB-cation-exchange cartridges with quantitative recoveries for all the analytes tested. However, matrix components of the surface water samples analysed negatively affected the recoveries of the analytes in the SDB-cation-exchange cartridge and thus, C18 cartridges were finally selected for the analysis of the (fluoro)quinolones in lake and river water. The limits of detection achieved with this procedure varied between 8 and 20 ng l(-1) proving its suitability for the determination of the (fluoro)quinolones in water samples at a realistic environmental concentration level.

1319. Tyler, A. (1956). Physico-chemical properties of the fertilizins of the sea urchin Arbacia punctulata and the sand dollar Echinarachnius parma. *Experimental Cell Research* 10: 377-386.
Chem Codes: Chemical of Concern: PSM Rejection Code: SURVEY.

Measurements have been made of the sedimentation rates, diffusion, viscosity and electrophoretic mobilities of the fertilizins of the sea urchin Arbacia punctulata and the sand dollar Echinarachnius parma. From the data for Arbacia a molecular weight of 280,000 is calculated, and a value of 300,000 considered more probable. The axial ratio is estimated to be 28 to 1, calculated for an unhydrated prolate ellipsoid and 20 to 1 if 0.4 gram of water is assumed to be bound per gram of fertilizin. The Echinarachnius fertilizin sedimented more slowly than that of Arbacia. The measurements of electrophoretic mobilities show these fertilizins to be highly acidic as had been found in other species. This data also permitted calculations of valence for Arbacia fertilizin as 14.25 effective negatively charged groups per molecule at pH 7 and 11.25 at pH 4.85. Measurements of the amount of fertilizin absorbed show that a single spermatozoon binds approximately 100,000 molecules, and therefore possesses at least that many receptor sites. The relation of this to certain features of fertilization is briefly discussed.

Hydrodynamic resistances of spheroidal porous agglomerates are calculated theoretically for circumstances when the flow is directed either parallel or perpendicular to their symmetry axes. Expressions for the equivalent mobility radii of oblate and prolate spheroids are calculated and generalized for wide ranges of particle porosities, sizes and fractal dimensions Df. Aggregate shape and permeability are shown to have competitive effects on their mobility. Permeability has the strongest effect on the mobility radii of agglomerates with shapes close to spherical and for extremely porous structures. For fractal-like agglomerates, permeability has the strongest effects for low Df structures, composed of about several hundreds of elementary particles. Mobility radii of these agglomerates are found to have fractal dimensions about 10% higher than the one that could be obtained from the geometrical size analysis. Large fractal agglomerates behave like impermeable bodies even if their average porosity is large. A similar behavior is characteristic of very small agglomerates, because their porosity is normally low. The calculated mobility radii are used for correlating the size-dependent free fall velocity of porous ice crystals. Citations: Zartarian, V; J Expo Anal Environ Epidemiol 1995, 5, 21 This study was undertaken to assess the exposure to organophosphate (OP) pesticides in children from peri-urban areas of the Province of Quebec, Canada, through measurements of semi-specific alkylphosphate (AP) metabolites. Eighty-nine children aged between 3 and 7 years were recruited via pamphlets sent to day-care centers. A first morning urine void was collected early in the spring of 2003 prior to summertime, which is the usual period of outdoor pesticide use. During summertime, up to five more first morning voids were repeatedly collected, at 72-h intervals, over a 13-day period. The potential determinants of exposure were assessed by a questionnaire at the time of urine collection.

Results: Methylphosphate metabolites were detectable in 98.2% of the 442 samples analyzed while ethylphosphates were detected in 86.7% of the samples. The geometric mean concn. (GM) of the total AP metabolites was 61.7 mg/g creatinine (range: 2.7-1967.3 mg/g creatinine). The difference in urinary AP concns. between samples collected during spring and summer was non-significant (P = 0.08). There was also no significant difference in the mean AP concns. between summer samples of individuals living in municipalities where outdoor pesticide use is or is not restricted (P = 0.25). However, the presence of a pet in the house was assocd. with an increase in AP concns. during spraying season (P = 0.02). Pesticides were seldom used, as reported by the questionnaire. A significant correlation was also obsd. (P < 0.001) between the urinary AP concns. in samples provided by siblings at the same time period. Conclusions: Mean concns. of AP were generally higher than those reported in other studies. The obsd. exposure apparently occurred mainly through the dietary ingestion of OP residues. These data raise questions on the levels of OP residues in Quebec food and the possibility that our participants consumed more fruits and vegetables than those in other studies. 1325. Van Cuyk, S., Siegrist, R., Logan, A., Masson, S., Fischer, E., and Figueroa, L. (Hydraulic and Purification Behaviors and Their Interactions During Wastewater Treatment in Soil Infiltration Systems. *Water res. 2001, mar; 35(4):953-64. [Water research]: Water Res.*
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE, CHEM METHODS.

ABSTRACT: Four three-dimensional lysimeters were established in a pilot laboratory with the same medium sand and either an aggregate-laden (AL) or aggregate-free (AF) infiltration surface and a 60- or 90-cm soil vadose zone depth to ground water. During 48 weeks of operation, each lysimeter was dosed 4 times daily with septic tank effluent (STE) at 5 cm/d (AL) or 8.4 cm/d (AF). Weekly monitoring was done to characterize the STE, percolate flow and composition, and water content distributions within the lysimeters. Bromide tracer tests were completed at weeks 0, 8, and 45 and during the latter two times, ice nucleating active (INA) bacteria and MS-2 and PRD-1 bacteriophages were used as bacterial and viral surrogates. After 48 weeks, soil cores were collected and analyzed for chemical and microbial properties. The observations made during this study revealed a dynamic, interactive behavior for hydraulic and purification processes that were similar for all four lysimeters. Media utilization and bromide retention times increased during the first two months of operation with the median bromide breakthrough exceeding one day at start-up and increasing to two days or more. Purification processes were gradually established over four months or longer, after which there were high removal efficiencies (>90%) for organic constituents, microorganisms, and virus, but only limited removal of nutrients. Soil core analyses revealed high biogeochemical activity within the infiltrative zone from 0 to 15 cm depth. All four lysimeters exhibited comparable behavior and there were no significant differences in performance attributable to infiltrative surface character or soil depth. It is speculated that the comparable performance is due to a similar and sufficient degree of soil clogging genesis coupled with bioprocesses that effectively purified the wastewater effluent given the adequate retention times and high volumetric utilization's of the sand media.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. The determination of arsenic in environmental samples suffers interference by chloride which gives rise to the polyatomic interference of

40Ar35Cl on 75As. Mathematical correction methods based on the ratios 40Ar37Cl/40Ar35Cl, 35Cl16O/40Ar35Cl or 37Cl16O/40Ar35Cl, are discussed and compared with each other. The method is applied to the determination of arsenic in treated percolate water from a landfill where arsenic containing waste is landfilled. The results obtained when applying the different equations were in good agreement with each other. The results for the untreated percolate water, which could be diluted far enough to eliminate matrix effects and showed negligible interference from chloride, were in good agreement with results obtained with Capillary Zone Electrophoresis. Hydride generation made it possible to determine As(III) and by difference As(V) in both waters. 99.7% of the arsenic present in the percolate water was As(V), which means that during the lan

1327. van der Salm, C., Verstraten, J. M., and Tiktak, A. (1996). The influence of percolation rate on the weathering rates of silicates in an E horizon of an Umbric Albaqualf. *Geoderma* 73: 83-106.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

Weathering rates of silicates obtained from laboratory experiments are generally one or two orders of magnitude higher than field weathering rates. To obtain more information on this gap in weathering rates a large undisturbed soil column (length 30 cm and a surface area of 113 cm2) was percolated with a HCl/H2SO4 solution. Percolation rates during the experiment were reduced in three steps from 0.89 to 0.15 cm d-1. A dynamic multi-layer model including transient flow, hydrodynamic dispersion, geochemical transformations and equilibria was utilized to simulate the percolate from the soil column. During the experiment weathering rates decreased by a factor of 5.6 upon a reduction in percolation rate. This reduction could only be partly explained by changes in saturation indices or by depletion of reactive components. The results could be simulated by assuming the following relationship between weathering and percolation rate: weathering FLUX = weathering rate x (H)[gamma] x (percolation rate)[beta]. This phenomenon is probably caused by the fact that at low percolation rates water stagnates in part of the pores and weathering rates reduce due to saturation, whereas in other pores water is quickly replaced and weathering rates remain constant. Results showed that the best fit to the observed data was obtained with a value of 0.5 for [gamma] and 1.2 for [beta]. The obtained relationship was utilized to scale the weathering rate obtained from' the column experiment to field conditions with lower average soil water fluxes and to laboratory experiments (pH-stat) with much higher percolation fluxes. Estimated weathering rates for field conditions and pH stat experiments were close to observed values.

ABSTRACT: In setting criteria for landfill classes in Annex II of the EU Landfill Directive, it proved to be impossible to derive criteria for stabilised monolithic waste due to the lack of information on release and release controlling factors in stabilised waste monofills. In this study, we present a scientific basis, which enables a realistic description of the environmental impact of stabilised waste landfills.The work in progress involves laboratory testing of different stabilisation recipes, pilot scale studies on site and evaluation of field leachate from a full-scale stabilisation landfill. We found that the pHs in run-off and in percolate water from the pilot experiment are both around neutral. The neutral pH in run-off is apparently caused by the rapid atmospheric carbonation of those alkaline constituents that are released. The soil, used as a liner protection layer, controls the release to the subsurface below the landfill. This soil layer buffers pH and binds metals. The modelling results show that the chemistry is understood rather well. Differences between predicted and actual leaching might then be attributed to discrepancies in the description of sorption processes, complexation to organic matter and/or kinetic effects in the leaching tests. We conclude that this approach resulted in a new scientific basis for environmental impact assessment of stabilised waste landfills. The integrated approach has already resulted in a number of very valuable observations, which can be used to develop a sustainable landfill for monolithic waste and to provide guidance for the management of waste to be stabilised (e.g. improved waste mix design).

1330. van Domelen, B. H. and Beeman, W. W. (1962). X-ray studies on top component a and bottom component of alfalfa mosaic virus. *Biochimica et Biophysica Acta (BBA) - Specialized Section on Nucleic Acids and Related Subjects* 61: 872-875.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS, VIRUS.

Small-angle X-ray-scattering measurements have been made on dilute solutions of two of the separated components of alfalfa mosaic virus. Top component a has an electronic radius of gyration of 129 A and bottom component 216 A. These results are accurate to about 5%. The extended scattering curve is in best agreement with a prolate, roughly cylindrical, shape for each particle. Top component a has a diameter of about 230 A and a length of 350 A. For bottom component the diameter is 220 A and the length 700 A. These results are not as reliable as the radii of gyration. Rather large hydrations are indicated for both particles. http://www.sciencedirect.com/science/article/B73G7-482YMPX-12/2/2ff73f720669ac76ac1d5641810b4b1a

1331. Varga, Laszlo, Pietruszkiewicz, Adolph, and Ryan, Marion (1959). Studies on hyaluronic acid : I. The influence of ionic strength on the sedimentation and diffusion properties. *Biochimica et Biophysica Acta* 32: 155-165.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Hyaluronic acid was prepared by an electrophoretic separation technique. This was considered to be the mildest possible method of preparation and the method least likely to cause any changes during preparation. The following physicochemical parameters were obtained: Sedimentation constant, s20 = 3.1 S; diffusion constant, D20 = 1.25[middle dot]10-7 cm2/sec; intrinsic viscosity, [[eta]] = 7.0. From these values we were able to calculate a molecular weight of M = 178,000 and a hydrodynamically effective volume of Ve = 1.0 ml/g, indicating a hydration of about 30%. On this basis and on the assumption that the shape of the molecule approximates the shape of a prolate ellipsoid of revolution, the molecular length was calculated to be L = 1900 A and the diameter of maximal circumference, d = 17.5 A. A frequency distribution coefficient of [gamma] = 0.44 was calculated from the spread of the sedimentation patterns. It was found that hyaluronic acid satisfies the Huggins equation when the constant k' = 0.275. The sedimentation and diffusion characteristics of hyaluronic acid have been studied as a function of ionic strength. It was found that these properties are very sensitive to changes in ionic strength, with the dependence most marked as zero ionic strength is approached. However, the changes induced by varying the ionic strength are perfectly reversible. Changes in temperature had no effect within the range investigated. http://www.sciencedirect.com/science/article/B73G9-47DXTD1-1HJ/2/e1b36051e751b9b37d48c0b5e106d33b

ABSTRACT: In this paper two different procedures for radon mapping have been compared on the same database referring to indoor radon records of South Tyrol. The first procedure is based on descriptive statistics applied to administrative units while the second one implies a more complicated statistical analysis applied to a regular grid: it involves floor level normalization of radon data, filling and smoothing algorithms for the territory cells.

ABSTRACT: In this paper a modern statistical technique of multivariate analysis is applied to an indoor radon concentration data base. Several parameters are more or less significant in determining the radon concentration inside a building. The elaboration of the information available on South Tyrol makes it possible both to identify the statistically significant variables and to build up a statistical model that allows us to forecast the radon concentration in dwellings, when the values of the same variables involved are given. The results confirm the complexity of the phenomenon.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. In this paper a scheme is presented that makes it possible to classify a large number of organic pollutants into one of four classes, viz: (1) inert chemicals, (2) less inert chemicals, (3) reactive chemicals and (4) specifically acting chemicals. For chemicals that are thus classified as belonging to one of these four classes it is possible to calculate either an expected effect concentration (inert chemicals), such as the LC50, or an expected range of possible effect concentrations, from a compound's octanol/water partition coefficient (Log Kow). For chemicals that cannot be classified as belonging to one of the four classes no prediction can be made. This approach can be implemented to estimate aquatic effect concentrations, which can be used to derive preliminary environmental quality objectives, or for the prioritisation of chemicals for subsequent testing. Moreover, these estimates could be of great value in risk and hazard assessment. To our opinion, this approac

1342. Vigot, R. and Batini, C. (Purkinje Cell Inhibitory Responses to 3-Appa (3-Aminopropylphosphinic Acid) in Rat Cerebellar Slices. *Neurosci res. 1999, aug; 34(3):141-7. [Neuroscience research]: Neurosci Res.*
Chem Codes: Chemical of Concern: PSM Rejection Code: IN VITRO.

ABSTRACT: 3-APPA is considered to be a GABA(B) agonist more potent than baclofen. We report here the results obtained by applying this agonist to Purkinje cells (PCs) recorded in current clamp mode on cerebellar slices. The responses were compared to those obtained with other GABA agonists and antagonists. The drugs were delivered either in the perfusion solution or by pressure to the molecular layer near the recorded cell. When applied to the PCs either in the bathing medium or by pressure, 3-APPA evoked a potent inhibitory response which was however

different from that obtained with baclofen. The response was complex and similar to that evoked by application of GABA, the endogenous neurotransmitter. In fact it showed: (1) very sensitive dose-response not affected by TTX in the bath; (2) an equilibrium potential compatible with Cl- channel conductance; (3) a massive reduction with the competitive GABA(A) antagonist bicuculline; (4) a small reduction, if any, with the potent competitive GABA(B) antagonist CGP55845A; (5) persistence of the responses under 4-AP (4-aminopyridine), the potassium channel blocker, and inhibition of the 4-AP-induced calcium bursts of spikes. The conclusion was reached that the inhibitory response of PCs to 3-APPA is induced, like GABA inhibition, by binding to both GABA(A) and GABA(B) postsynaptic receptors.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. When investigating a toxic and potentially mutagenic effect of fosmet, an active component of organophosphate insecticide of Decemtion EK-20, and a mixture of solvents on eukaryotic microorganisms Saccharomyces cerevisiae D7 the following could be found: 1. The toxic effect of both fosmet and the mixture of solvents rose with the increase of the dose. 2. Fosmet exhibited an increased frequency of all genetic changes investigated, i.e. of mitotic crossing-over, mitotic gene conversion and reverse mutations. The frequency of the gene reverse mutations was increased in the most distinct way (7-fold). 3. At the highest concentration of the solvent mixture used, a slight increase of the frequency in all genetic changes investigated could be stated.

1346. Vogel, Manfred and Heinz, Fritz (1981). Purification and characterisation of the cyclic amp-dependent protein kinase, the C- and the R-protein from bovine liver. *Biochimica et Biophysica Acta (BBA) - Protein Structure* 670: 47-55.
Chem Codes: Chemical of Concern: PSM Rejection Code: IN VITRO.

A cyclic AMP-dependent protein kinase, its regulatory (R) and catalytic (C) protein were isolated from bovine liver. The cyclic AMP-dependent protein kinase showed two protein bands on SDS-polyacrylamide gel electrophoresis with molecular weights of 54 000 and 40 000. They correspond to the data for the separately isolated R- and C-protein. The molecular weight of the holoenzyme ranged from 172 000-179 000, depending on the estimation method. The molecular

weight of the R-protein ranged from 97 000-98 000. This, and the results of the SDS-polyacrylamide gel electrophoresis, demonstrates a dimeric structure. The frictional ratios (f/f0) of 1.67-1.7 for the holoenzyme and 1.9 for the R-protein correspond to highly asymmetric shapes. Assuming a prolate form, the axial ratios are 13-14 and 17, respectively. The C-protein is globular (f/f0 1.1-1.26, axial ratio 3-5). The seondary structure with 35% [alpha]-helix, 19% [beta]-sheet and 49% aperiodic form of the holoenzyme is similar to the R-protein with 35, 19 and 46%, respectively. The C-protein contains 29% [alpha]-helix, 21% [beta]-sheet and 50% aperiodic form. The dimeric R-protein binds 4 mol cyclic AMP and can be phosphorylated in the presence of the C-protein. An absorption coefficient, A280nm1.0%, of 5.4 was calculated for the R-protein and of 13.6 for C-protein. The data for C-protein, e.g., molecular weight, heterogeneity in isoelectrofocusing, phosphate content, etc., are in good agreement with those found by Sudgen, P.H. and Corbin, J.D. (1976) Biochem. J. 159, 423-437. Protein kinase/ Cyclic AMP/ Regulatory protein/ Catalytic protein/ Secondary structure/ (Bovine liver)

1347. Vogt, R. D., Seip, H. M., Larssen, T., Zhao, D., Xiang, R., Xiao, J., Luo, J., and Zhao, Y. (Potential Acidifying Capacity of Deposition Experiences From Regions With High Nh4+ and Dry Deposition in China. *Sci total environ. 2006, aug 15; 367(1):394-404. [The science of the total environment]: Sci Total Environ.*
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: Acid rain may cause soil acidification possibly leading to indirect forest damage. Assessment of acidification potential of atmospheric deposition is problematic where dry and occult deposition is significant. Furthermore, uncertainty is enhanced where a substantial part of the potential acidity is represented by deposition of ammonium (NH(4)(+)) since the degree of assimilation and nitrification is not readily available. Estimates of dry deposition based on deposition velocity are highly uncertain and the models need to be verified or calibrated by field measurements of total deposition. Total deposition may be monitored under the forest canopy. The main problem with this approach is the unknown influence of internal bio-cycling. Moreover, bio-cycling may neutralize much of the acidity by leaching of mainly K(+). When the water percolates down into the rooting zone this K(+) is assimilated again and acidity is regenerated. Most monitoring stations only measure deposition. Lacking measurements of output flux of both NH(4)(+) and NO(3)(-) from the soil one cannot assess current net N transformation rates. Assumptions regarding the fate of ammonium in the soil have strong influence on the estimated acid load. Assuming that all the NH(4)(+) is nitrified may lead to an overestimation of the acidifying potential. In parts of the world where dry deposition and ammonium are important special consideration of these factors must be made when assessing the acidification potential of total atmospheric loading. In China dry and occult deposition is considerable and often greater than wet deposition. Furthermore, the main part of the deposited N is in its reduced state (NH(4)(+)). The IMPACTS project has monitored the water chemistry as it moves through watersheds at 5 sites in China. This paper dwells at two important findings in this study. 1) Potassium leached from the canopy by acid rain is assimilated again upon entering the mineral soil. 2) Nitrification apparently mainly takes place in forest floor (H- and O-) horizon as NH(4)(+) that escapes this horizon is efficiently assimilated in the A-horizon. This suggests that the potential acidification capacity of the deposition may be found in the throughfall and forest floor solution by treating K(+) and NH(4)(+), respectively, as acid cations in a base neutralization capacity (BNC) calculation.

The results clearly demonstrate that fragmentation in the TSP mass spectra of the investigated pesticides was mainly caused by gas- or liq.-phase chem. dissocn. reactions of neutral analyte mols. or, in some instances, of the quasi-mol. ions in the ion source or the vaporizer probe, probably induced by solvent or buffer ions which can be described by well defined mechanisms. A linear relationship was obsd. for most of those pesticides which showed combinations of the two quasi-mol. ions $[M+H]^+$ and $[M+NH_4]^+$, when the logarithm of the ion abundance ratio for the $[M+H]^+$ ion relative to the $[M+NH_4]^+$ ion was plotted against the reciprocal of the abs. temp. of the gas phase. It is shown that this dependence can be used to generate TSP mass spectra with mainly one quasi-mol. ion. This may be of value for selected-ion monitoring expts., because the total ion current (i.e., the sum of the $[M + H]^+$ and $[M + NH_4]^+$ ions) is less dependent on the gas-phase temp. than the ion currents of the individual quasi-mol. ions. It was found that addnl. adduct ions beside these quasi-mol. ions could be obsd. in the spectra of several pesticides for which the formation was limited to low gas-phase temps. In addn., the results for the investigated quaternary ammonium compds. clearly show that the addn. of a volatile buffer salt to the mobile phase induces chem. reactions in the gas phase which have a strong influence on the ion abundances. However, addn. of buffer salt was necessary to obtain intense signals although the compds. are already completely dissocd. in the aq. solvent and fragmentation was enhanced as the buffer concn. was raised. The method described includes 108 pesticides and some of their degrdn. products. Evaluation of important exptl. parameters affecting the HPLC-MS detn. of relevant pesticides and trace enrichment from aq. samples is described. Preconcn. is achieved by either off-line or online solid-phase extn. with subsequent HPLC sepn. Verification of the limit of German and EU Drinking Water Guidelines (100 ng/L) for all investigated compds. and detection limits in the low ng/L range are obtained. The method was evaluated with respect to its selectivity, detection limit, linearity, precision, and ruggedness. [on SciFinder (R)] 0083-6915

The sensitivity and the selectivity of this method for the detn. of 128 pesticides having a wide range of structures and polarities were

investigated. An LC sepn. in combination with postcolumn addn. of a volatile salt soln. was developed, which permits the anal. of 95 pesticides with a single LC-MS method using reversed-phase gradient elution. The retention data and TSP mass spectra of these compds. are presented. The advantages of TSP postcolumn techniques in comparison with conventional systems are discussed. The application of this method to the anal. of an environmental sample (river water) spiked with 8 phenylureas is demonstrated. The method was evaluated with respect to detection limit, linearity and reproducibility. In addn., a simple method for enhancing the structural information from TSP spectra is reported, which makes use of specific instabilities found with many pesticides. As an example, possibilities for the confirmatory anal. of carbamates are described. In this context, a pragmatic approach is to discriminate excess toxicity from narcotic effect levels, because the latter can be estd. from QSARs and thus have a low priority for exptl. testing. To develop a resp. scheme for the acute daphnid toxicity as one of the primary ecotoxicol. endpoints, 1067 acute toxicity data entries for 380 chems. involving the daphnid species Daphnia magna were taken from the online literature, and quality checks such as water soly. were employed to eliminate apparently odd data entries. For 36 known narcotics with LC50 values referring to D. magna, a ref. baseline QSAR is derived. Compds. with LC50 values above a certain threshold defined relative to their predicted baseline toxicity are classified as exerting excess toxicity. Three simple discrimination schemes are presented that enable the identification of excess toxicity from structural alerts based on the presence or absence of certain heteroatoms and their chem. functionality. Moreover, a two-step classification approach is introduced that enables a prioritization of org. compds. with respect to their need for exptl. testing. The discussion includes reaction mechanisms that may explain the assocn. of structural alerts with excess toxicity, a comparison with predictions derived from mode of action-based classification schemes, and a statistical anal. of the discrimination performance in terms of detailed contingency table statistics. Chem Codes: Chemical of Concern: PSM Rejection Code: NON-ENGLISH.

ABSTRACT: Phthalophos, organophosphoric pesticide, in the perfused isolated liver of rats transforms to water-soluble oxymethyl phthalimide and phthalimide. The induction of the liver hydroxylating enzymic system with milbex accelerates transformation of phthalophos: in 5 min only 14% of its initial amount is found in perfusate, while in the control--52%. The inhibition of the hydroxylating enzymic system with tetramethylthiuramdisulphide (dithiocarbamate pesticide) inhibits transformation of phthalophos: in 15 min perfusate contains 33% of its initial amount and the control--16%. Induction and inhibition of the hydroxylating enzymic system of the liver affect essentially the phthalophos toxicodynamics, decreasing the degree of the cholinesterase activity.

ABSTRACT: PESTAB. The effect of induction and inhibition of liver hydroxylating enzymes on the rate of phthalophos (phosmet) degradation was studied in the perfused rat liver. Random-bred rats were subjected to a po daily administration of the organochlorine pesticide milbex at 0.2 LD50 (to induce the hydroxylating enzyme system) or the dithiocarbamate pesticide tetramethylthiuramdisulfide (TMTD, thiram) at 0.2 LD50 (to inhibit the hydroxylating enzyme system). Pesticides were given for 3 days. Two days after termination of pesticide administration, rats were sacrificed and the isolated perfused liver was exposed to phthalophos at 8 mug/ml of perfusate. It was found that the hydroxylating enzyme system had a significant effect on the rate of phthalophos degradation. Milbex enhanced phthalophos degradation, while TMTD delayed phthalophos degradation.

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: PESTAB. Studies on the migration of pesticides in the biosphere are reviewed. The ability of certain pesticides to migrate in water was found to decrease in the order DDT, polychloropinene (strobane), melprex (dodine), phosalone, lindane, and phthalophos (phosmet). the migration of DDT from the soil into plants is highest for root crops, such as carrots and potatoes (4-25%), and lowest for corn (2%) and cabbage (0.3-0.6%), and increases with the DDT level in the soil. Carbaryl was found to persist for 1-2 years in soil and for 0.5-3 months in plants grown in soil containing carbaryl.

1356. Vrochinskiy, K. K. (Migratory Properties of Pesticides in a Model Water Ecosystem. *Ryb. Khoz.11: 29-31; 1973.*
Chem Codes: Chemical of Concern: PSM Rejection Code: NON-ENGLISH.

ABSTRACT: PESTAB The stability and migration of 11 different pesticides in model ecosystems (water, water with fish, and water with silt and aquatic plants) were studied in a 30-day experiment. The stability of the pesticides in water without aquatic organisms decreased in the order lindane, DDT, polychlorocamphene, toxaphene abate, baytex fenthion, fenuron,

trichlorometaphos-3 (ronnel), melprex dodine, polycarbazine, phosalone, and phthalophos phosmet. The cumulation factors determined in silt, aquatic plants, and fish were in the respective ranges of 0. 4-800, 0. 4-3,550, and 0. 4-1,870. The cumulation factors were under 50 for phthalophos and over 1,000 for DDT and polychlorocamphene. Adsorption and secondary desorption, i. e. , circulation of the pesticides in the water ecosystem rather than self-purification, were observed, especially in the case of the most hazardous pesticidesöDDT, polychlorocamphene, melprex, and phosalone.

Section Title: Agrochemical Bioregulators
Coden: PIXXD2
Index Terms: Terpenes Role: AGR (Agricultural use), BIOL (Biological study), USES (Uses) (chloro-, mixts. with pyrazole derivs.; synergistic fungicidal compns.); Naphthenic acids Role: AGR (Agricultural use), BIOL (Biological study), USES (Uses) (copper salts, mixts. with pyrazole derivs.; synergistic fungicidal compns.); Cedar (ext., mixts. with pyrazole derivs.; synergistic fungicidal compns.); Fats and Glyceridic oils Role: AGR (Agricultural use), BIOL (Biological study), USES (Uses) (margosa, ext., mixts. with pyrazole derivs.; synergistic fungicidal compns.); Bacillus pumilus; Bacillus subtilis; Ryania; Trichoderma; Trichoderma harzianum; Trichoderma virens; Xanthomonas campestris vesicatoria (mixts. with pyrazole derivs.; synergistic fungicidal compns.); Cytokinins; Paraffin oils; Petroleum; Pyrethrins Role: AGR (Agricultural use), BIOL (Biological study), USES (Uses) (mixts. with pyrazole derivs.; synergistic fungicidal compns.); Quassia; Tar oils (mixts. with pyrazole derivs; synergistic fungicidal compns.); Fungicides (synergistic; compns. comprising a pyrazole deriv.); Toxins Role: AGR (Agricultural use), BIOL (Biological study), USES (Uses) (d-endotoxins, mixts. with pyrazole derivs.; synergistic fungicidal compns.)
CAS Registry Numbers: 688-73-3D Role: AGR (Agricultural use), BIOL (Biological study), USES (Uses) (Tributyltin; synergistic fungicidal compns.); 881685-73-0; 881685-74-1; 881685-75-2; 881685-76-3; 881685-77-4; 881685-78-5; 881685-79-6 Role: AGR (Agricultural use), BIOL (Biological study), USES (Uses) (synergistic fungicidal compn.); 50-00-0D (Formaldehyde); 50-14-6D (Ergocalciferol); 50-29-3D; 50-65-7D (Niclosamide;); 51-03-6D (Piperonyl butoxide;); 51-14-9D (Sesamex); 52-46-0D (Apholate); 52-68-6D (Trichlorfon); 54-11-5D (Nicotine;); 56-35-9D (Bis(tributyltin)oxide;); 56-38-2D (Parathion); 56-72-4D (Coumaphos); 57-92-1D (Streptomycin); 58-89-9D (Lindane); 60-51-5D (Dimethoate); 62-73-7D (Dichlorvos); 63-25-2D (Carbaryl); 65-30-5D (Nicotine sulfate;); 66-81-9D (Cycloheximide); 67-66-3D (Chloroform); 67-97-0D (Cholecalciferol); 70-43-9D (Barthrin); 71-62-5D (Veratridine;); 72-56-0 (1,1-Dichloro-2,2-bis(4-ethylphenyl)ethane;); 74-83-9D (Methyl bromide); 74-88-4D (Iodomethane); 74-90-8D (Hydrogen cyanide;); 75-15-0D (Carbon disulfide); 76-06-2D (; Chloropicrin;); 76-44-8D (Heptachlor); 76-87-9D (Triphenyltin hydroxide); 78-34-2D (Dioxathion); 78-53-5D (Amiton); 78-87-5D (1,2-Dichloropropane;); 79-57-2D (Terramycin); 80-00-2D (4-Chlorophenyl phenyl sulfone); 80-06-8D (Chlorfenethol); 80-33-1D (Chlorfenson); 80-38-6D (Fenson); 81-81-2D (Warfarin); 81-82-3D (Coumachlor); 82-66-6D (Diphacinone;); 82-68-8D (Pentachloronitrobenzene); 83-26-1D (Pindone); 83-79-4D (Rotenone); 84-65-1D (Anthraquinone;); 84-74-2D (Dibutyl phthalate;); 86-50-0D (Azinphos methyl); 86-88-4D (ANTU); 87-47-8D (3-Methyl-1-phenylpyrazol-5-yl dimethylcarbamate;); 87-86-5D (Pentachlorophenol); 92-52-4D (Biphenyl); 93-15-2D (Methyleugenol); 93-75-4D (Thioquinox); 95-05-6D (Sulfiram); 97-16-5D; 97-53-0D (Eugenol); 97-77-8D (Disulfiram); 99-30-9D (Dichloran); 101-05-3D (Anilazine); 103-17-3D (Chlorbenside); 103-33-3D (Azobenzene); 104-55-2D (Cinnamaldehyde); 105-99-7D (Dibutyl adipate;); 107-04-0D (1-Bromo-2-chloroethane;);

107-13-1 (Acrylonitrile;); 107-49-3D (TEPP); 108-62-3D (Metaldehyde;); 112-80-1D (Oleic acid;); 113-48-4D (MGK 264;); 114-26-1D (Propoxur); 115-26-4D (Dimefox); 115-29-7D (Endosulfan); 115-32-2D (Dicofol); 116-01-8D (Ethoate-methyl); 116-06-3D (Aldicarb); 116-29-0D (Tetradiphon); 117-18-0D (Tecnazene); 117-52-2D (Coumafuryl;); 117-80-6D (Dichlone); 118-74-1D (Hexachlorobenzene); 119-12-0D (Pyridaphenthion); 120-51-4D (Benzyl benzoate); 120-62-7D (Sulfoxide;); 120-93-4D (2-Imidazolidone;); 121-20-0D (Cinerin II); 121-21-1D (Pyrethrin I); 121-29-9D (Pyrethrin II); 121-75-5D (Malathion); 122-15-6D; 126-75-0D (Demeton-s); 127-09-3D (Sodium acetate); 127-63-9D (Diphenyl sulfone); 127-90-2D (S421); 131-11-3D (Dimethyl phthalate;); 131-89-5D (Dinex); 133-07-3D (Folpet); 134-31-6D (8-Hydroxyquinoline sulfate); 134-62-3D (Diethyltoluamide); 135-58-0D (Mesulfen); 137-30-4D (Ziram); 137-40-6D (Sodium propionate); 140-56-7D (Fenaminosulf); 140-57-8D (Aramite); 141-03-7D (Dibutyl succinate); 141-66-2D (Dicrotophos); 144-41-2D (Morphothion); 144-55-8D (Sodium bicarbonate); 148-79-8D (Thiabendazole); 152-16-9D (Schradan); 298-00-0D (Parathionmethyl;); 298-02-2D (Phorate); 298-03-3D (Demeton-O); 298-04-4D (Disulfoton); 298-14-6D (Potassium bicarbonate); 300-76-5D (Naled); 301-11-1D (2-Thiocyanatoethyl laurate;); 302-49-8D (Uredepa); 309-00-2D (Aldrin); 311-47-7D (2-Chlorovinyl diethyl phosphate;); 315-18-4D (Mexacarbate); 317-83-9D (Dinex-diclexine); 333-20-0D (Potassium thiocyanate;); 333-41-5D (Diazinon); 371-86-8D (Mipafox); 405-30-1D (Fluorbenside); 470-90-6D (Chlorfenvinphos); 471-47-6D; 483-63-6D (Crotamiton); 485-31-4D (Binapacryl); 494-52-0D (Anabasine;); 500-28-7D; 504-24-5D (4-Pyridinamine); 507-60-8D (Scilliroside); 510-15-6D (Chlorobenzilate); 525-79-1D (Kinetin;); 526-07-8D (Sesamolin); 532-34-3D (Butopyronoxyl); 533-74-4D (Dazomet); 534-52-1D (DNOC); 535-89-7D (Crimidine); 555-89-5D (DCPM); 556-22-9D (Glyodin); 563-12-2D (Ethion); 584-79-2D (Bioallethrin); 592-01-8D (Calcium cyanide); 594-72-9D (1,1-Dichloro-1-nitroethane;); 639-58-7D (Fentin chloride); 640-15-3D (Thiometon); 640-19-7D (Fluoroacetamide); 671-04-5D (Carbanolate); 682-80-4D (Demephion-O); 731-27-1D (Tolylfluanide); 732-11-6D (Phosmet); 780-11-0D (Terbam); 786-19-6D (Carbophenothion); 867-27-6D (Demeton-O-methyl); 900-95-8D (Fentin acetate); 919-54-0D (Acethione;); 919-76-6D (Amidithion); 919-86-8 (Demeton-S-methyl); 947-02-4D (Phospholan); 950-10-7D (Mephosfolan); 950-37-8D (Methidathion); 973-21-7D (Dinobuton); 991-42-4D (Norbormide;); 999-81-5D (Chlormequat chloride); 1031-47-6D; 1085-98-9D (Dichlofluanid); 1113-02-6D (Omethoate); 1121-30-8D; 1129-41-5D (Metolcarb); 1172-63-0D (Jasmolin II); 1303-96-4D (Borax); 1305-62-0D (Hydrated lime); 1314-84-7D (Zinc phosphide;); 1327-53-3D (Arsenous oxide); 1332-40-7D (Copper oxychloride;); 1344-81-6D (Calcium polysulfide); 1420-04-8D (Niclosamide ethanolamine salt); 1563-66-2D (Carbofuran); 1569-60-4D (Sulcatol;); 1646-88-4D (Aldoxycarb); 1715-40-8D (Bromocyclen); 1776-83-6D (Quinthiophos); 1897-45-6D (Chlorothalonil); 2032-59-9D (Aminocarb); 2032-65-7D (Methiocarb); 2079-00-7D (Blasticidin-S); 2104-64-5D (EPN); 2104-96-3D (Bromophos); 2168-68-5D (Morzid); 2227-13-6D (Tetrasul); 2227-17-0D (Dienochlor); 2274-74-0D (Chlorfensulfide); 2275-14-1D (Phenkapton); 2275-18-5D (Prothoate); 2310-17-0D (Phosalone); 2312-35-8D (Propargite); 2425-06-1D (Captafol); 2425-10-7D (Xylylcarb); 2425-20-9D (Siglure); 2439-01-2D (Chinomethionat); 2439-10-3D (Dodine); 2497-07-6D (Oxydisulfoton); 2540-82-1D (Formothion); 2587-90-8D (Demephion-S); 2593-15-9D (Etridiazole); 2595-54-2D (Mecarbam); 2597-03-7D (Phenthoate); 2642-71-9D (Azinphos ethyl); 2655-14-3D (XMC;); 2668-92-0D; 2674-91-1D (Oxydeprofos); 2675-77-6D (Chloroneb); 2778-04-3D (Endothion); 2921-88-2D (Chlorpyrifos); 3244-90-4D; 3347-22-6D (Dithianon); 3547-33-9D (2-(Octylthio)ethanol;); 3572-06-3D (Cuelure); 3604-87-3D; 3653-39-2D (Hexamide); 3689-24-5D (Sulfotep); 3691-35-8D (Chlorophacinone;); 3734-95-0D (Cyanthoate); 3734-97-2D (Amiton oxalate); 3737-00-6D (3-Bromo-1-chloroprop-1-ene;); 3878-19-1D (Fuberidazole); 4104-14-7D (Phosacetim;); 4151-50-2D (Sulfluramid); 4301-50-2D (Fluenetil); 4466-14-2D (Jasmolin I); 4824-78-6D (Bromophos-ethyl); 5221-49-8D (Pyrimitate); 5221-53-4D (Dimethirimol); 5234-68-4D (Carboxin); 5259-88-1D (Oxycarboxin); 5289-74-7D (Ecdysterone); 5386-57-2D (Dinopenton); 5386-77-6D (Dinosulfon); 5598-13-0D (Chlorpyrifos-methyl); 5748-20-9D (Trimedlure B1;); 5748-21-0D (Trimedlure B2;); 5748-22-1D (Trimedlure A;); 5748-23-2D (Trimedlure C); 5834-96-8D (Azothoate); 5836-10-2D (Chloropropylate); 5903-13-9D; 6012-83-5D; 6073-72-9D (Dinoterbon); 6164-98-3D (Chlordimeform); 6392-46-7D (Allyxycarb;); 6923-22-4D (Monocrotophos); 6980-18-3D (Kasugamycin); 7076-53-1D; 7439-97-6D (Mercury); 7440-50-8D (Copper); 7487-94-7D (Mercuric chloride); 7561-71-9D (Trinactin); 7664-38-2D

Section Title: Agrochemical Bioregulators
Coden: PIXXD2
Index Terms: Terpenes Role: AGR (Agricultural use), BIOL (Biological study), USES (Uses) (chloro-, mixts. with pyrazole derivs.; synergistic fungicidal compns.); Polygonum sachalinense (ext., mixts. with pyrazole derivs.; synergistic fungicidal compns.); Fats and Glyceridic oils Role: AGR (Agricultural use), BIOL (Biological study), USES (Uses) (margosa, mixts. with pyrazole derivs.; synergistic fungicidal compns.); Bacillus pumilus; Bacillus thuringiensis; Quassia; Schoenocaulon; Tar oils; Trichoderma; Trichoderma harzianum; Trichoderma virens; Xanthomonas campestris vesicatoria (mixts. with pyrazole derivs.; synergistic fungicidal compns.); Arsenates; Cytokinins; Epoxides; Paraffin oils; Pyrethrins Role: AGR (Agricultural use), BIOL (Biological study), USES (Uses) (mixts. with pyrazole derivs.; synergistic fungicidal compns.); Petroleum products (oils, mixts. with pyrazole derivs.; synergistic fungicidal compns.); Fungicides (synergistic; compns. comprising pyrazole derivs.); Toxins Role: AGR (Agricultural use), BIOL (Biological study), USES (Uses) (d-endotoxins, mixts. with pyrazole

derivs.; synergistic fungicidal compns.)
CAS Registry Numbers: 101903-30-4D (Pefurazoate) Role: AGR (Agricultural use), BIOL (Biological study), USES (Uses) (7synergistic fungicidal compns.); 56196-53-3D (Oryctalure) Role: AGR (Agricultural use), BIOL (Biological study), USES (Uses) (Et 4-methyloctanoate; synergistic fungicidal compns.); 95465-99-9D (Sebuphos) Role: AGR (Agricultural use), BIOL (Biological study), USES (Uses) (Sebufos, Cadusafos; synergistic fungicidal compns.); 5748-23-2D (Trimedlure C) Role: AGR (Agricultural use), BIOL (Biological study), USES (Uses) (Trimedlure C; synergistic fungicidal compns.); 7696-12-0D (d-Tetramethrin;) Role: AGR (Agricultural use), BIOL (Biological study), USES (Uses) (d-Tetramethrin;; synergistic fungicidal compns.); 50-00-0D (Formaldehyde); 50-14-6D (Ergocalciferol;); 50-29-3D (DDT); 51-03-6D (Piperonyl butoxide;); 51-14-9D (Sesamex); 51-18-3D (Tretamine;); 52-24-4D (Thiotepa); 52-46-0D (Apholate;); 52-51-7D (Bronopol); 52-68-6D; 52-85-7D (Famphur); 54-11-5D (Nicotine); 54-64-8D (Thiomersal); 55-38-9D (Fenthion); 55-98-1D (Busulfan;); 56-23-5D (Carbon tetrachloride;); 56-35-9D (Bis(tributyltin)oxide;); 56-38-2D (Parathion); 56-72-4D (Coumaphos;); 57-24-9D (Strychnine); 57-39-6D (Metepa); 57-92-1D (Streptomycin;); 58-89-9D (Lindane;); 60-51-5D (Dimethoate); 60-57-1D (Dieldrin); 62-73-7D (Dichlorovos;); 63-25-2D (Carbaryl); 65-30-5D (Nicotine sulfate); 66-81-9D (Cycloheximide;); 67-66-3D (Chloroform); 67-97-0D (Cholecalciferol); 70-38-2D (Dimethrin;); 70-43-9D (Barthrin); 71-62-5D (Veratrine); 72-00-4D (2,2-Dichlorovinyl diethyl phosphate); 72-20-8D (Endrin;); 72-54-8D (TDE;); 72-56-0D (1,1-Dichloro-2,2-bis(4-ethylphenyl)ethane); 74-83-9D (Methyl bromide;); 74-88-4D (Iodomethane); 75-09-2 (Methylene chloride;); 75-15-0D (Carbon disulfide); 76-06-2D (Chloropicrin;); 76-87-9D (Triphenyltin hydroxide); 76-96-0D (Methiotepa); 78-34-2D (Dioxathion); 78-53-5D (Amiton;); 78-57-9D (Menazon;); 78-87-5D (1,2-Dichloropropane); 79-34-5D (Tetrachloroethane;); 79-57-2D (Terramycin); 80-00-2D (4-Chlorophenyl phenyl sulfone); 80-33-1D (Chlorfenson;); 80-38-6D (Fenson); 81-81-2D (Warfarin); 82-66-6D (Diphacinone;); 82-68-8D (Quintozene); 83-26-1D (Pindone;); 83-28-3D (2-Isovalerylindan-1,3-dione); 83-59-0D (Propyl isome); 83-79-4D (Rotenone); 84-65-1D (Anthraquinone); 84-74-2D (Dibutyl phthalate); 86-50-0D (Azinphosmethyl;); 86-88-4D (Antu); 87-47-8D (3-Methyl-1-phenylpyrazol-5-yl dimethylcarbamate;); 87-86-5D (Pentachlorophenol;); 91-20-3D (Naphthalene); 92-52-4D (Biphenyl); 93-15-2D (Methyleugenol;); 93-75-4D (Thioquinox); 95-05-6D (Sulfiram); 96-12-8D (DBCP); 97-11-0D (Cyclethrin); 97-16-5D (2,4-Dichlorophenyl benzenesulfonate;); 97-23-4D (Dichlorophen); 97-53-0D (Eugenol;); 97-77-8D (Disulfiram); 99-30-9D (Dicloran;); 101-05-3D (Anilazine;); 103-17-3D (Chlorbenside;); 103-33-3D (AZobenzene;); 104-55-2D (Cinnamaldehyde;); 105-99-7D (Dibutyl adipate); 106-46-7D (Paradichlorobenzene;); 106-93-4D (Ethylene dibromide;); 107-04-0D (1-Bromo-2-chloroethane;); 107-06-2D (Ethylene dichloride;); 107-13-1D (ACrylonitrile); 107-49-3D (TEPP); 108-60-1D (DCIP;); 108-62-3D (Metaldehyde); 109-94-4D (Ethyl formate;); 110-85-0D (Piperazine); 112-56-1 (2-(2-Butoxyethoxy)ethyl thiocyanate;); 112-80-1D (Oleic acid); 113-48-4D (MGK 264;); 114-26-1D (Propoxur); 115-26-4D (Dimefox); 115-29-7D (Endosulfan); 115-32-2D (Dicofol;); 115-93-5D (Cythioate); 116-01-8D (Ethoatemethyl); 116-06-3D (Aldicarb); 116-29-0D (Tetradifon); 117-18-0D (Tecnazene); 117-80-6D (Dichlone); 118-74-1D (Hexachlorobenzene); 119-12-0D (Pyridaphenthion); 120-51-4D (Benzyl benzoate); 120-62-7D (Sulfoxide); 120-93-4D (2-Imidazolidone); 121-20-0D (Cinerin II;); 121-21-1D (Pyrethrin I); 121-29-9D (Pyrethrin II;); 121-75-5D; 122-14-5D (Fenitrothion;); 122-15-6D; 122-34-9D (Simazine;); 126-22-7D (Butonate;); 126-75-0D (Demeton-S;); 126-96-5D (Sodium diacetate); 127-63-9D (Diphenyl sulfone); 127-90-2D (S421); 131-11-3D (Dimethyl phthalate;); 131-89-5D (Dinex); 133-06-2D (Captan;); 133-07-3D (Folpet;); 134-31-6D (8-Hydroxyquinoline sulfate;); 134-62-3D (Diethyltoluamide); 135-58-0D (Mesulfen;); 136-63-0D (Bucarpolate); 137-26-8D (Thiram); 137-30-4D (Ziram;); 137-40-6D (Sodium propionate); 137-41-7D; 137-42-8D (Metamsodium); 140-56-7D (Fenaminosulf;); 140-57-8D (Aramite); 140-89-6D (Potassium ethylxanthate;); 141-03-7D (Dibutyl succinate); 141-66-2D (Dicrotophos); 142-59-6D (Nabam); 143-50-0D; 144-41-2D (Morphothion); 144-55-8D (Sodium bicarbonate); 145-73-3D; 148-79-8D (Thiabendazole); 152-16-9D (Schradan); 297-78-9D (Isobenzan;); 298-02-2D (Phorate); 298-03-3D (Demeton-O;); 298-04-4D (Disulfoton); 298-14-6D (Potassium bicarbonate); 299-84-3D; 299-86-5D (Crufomate); 300-76-5D (Naled;); 301-11-1D (2-Thiocyanatoethyl laurate;); 301-12-2D (Oxydemeton-methyl); 302-49-8D (Uredepa); 309-00-2D (HHDN); 315-18-4D (Mexacarbate;); 317-83-9D (Dinex-diclexine); 327-98-0D (Trichloronat);

The effects of various operating parameters (e.g., mobile phase compn., flow-rate, and irradn. wavelength) on signal-to-noise output for selected compds. were evaluated. A comparison of photocond. responses with those obtained from a UV detector connected in tandem was made for selected ref. stds. and food sample exts. The photocond. detector was suitable for the detn. of pesticide residues at sub-parts-per-million levels. The linearity and reproducibility of the response are adequate for practical quant. applications. [on SciFinder (R)] 0021-9673

(GC) system, for trace anal. of org. pollutants in water. A 5 m * 0.53 mm, 1.2-mm df poly(dimethylsiloxane) phase capillary column was the in-tube extractor. This dynamic extn. method used a high sampling flow rate, thermal desorption, and valve switching in a novel system design. Compared with classic SPME, the online in-tube SPME system dramatically increased enrichment factors, and, due to online operation, improved quantitation precision. Cost/sample was the same as that of classic fiber SPME; it might be even lower in long-term use due to the use of an ordinary switching valve and conventional GC column extractor. The sample was extd. with ACN, and coextractives were removed with primary/secondary amine sorbent. ACN ext. (20 mL) was injected into a PTV injection port in solvent vent mode, and the pesticides were detd. by GC-MS using retention time locking software. Deuterium-labeled pesticides (surrogate stds.) were used for anal. quality control. In the validation expts., pesticides recoveries were found to be 70-121% with RSDs of 4.6-21% (n = 6). 1364. Wangen, L. E. and Jones, M. M. (Attenuation of Chemical Elements in Acidic Leachates From Coal Mineral Wastes by Soils. *Govt reports announcements & index (gra&i), issue 05, 1985*.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: TD3: The chemical attenuation of acidity and selected elements (aluminum, arsenic, cadmium, cobalt, chromium, copper, fluorine, iron, manganese, nickel, and zinc) in acidic leachates from coal mineral wastes by four natural subsurface soils has been investigated by using laboratory column methods. Leachate solutions were allowed to percolate through the soils under simulated natural flow conditions, and the elemental concentrations in the influents and effluents were measured periodically. Elemental retentions were substantial for all species except manganese, which was eluted in excess from all soils except the most calcerous. Two processes appeared to operate in decreasing influent concentrations: (1) precipitation of solid phases caused by increased pH of the leachate as it percolated through the soil, and (2) adsorption of elements onto exchange and sorption sites naturally present in the soil and on iron and aluminum oxide precipitates formed in situ from leachate components because of the incre

Patent Application Country: Application: US
Priority Application Country: WO
Priority Application Number: 2004-US17627
Priority Application Date: 20040603 An emulsion comprising water as the continuous phase, a wax as the discontinuous phase, an emulsifier and a preservative having the general structure: wherein R1 can be a heterocycle contg. nitrogen and sulfur, such as thiazolyl, isothiazolyl, or thiadiazolyl, which can optionally be substituted with C1-C6 alkyl; R2 can be hydrogen or C1-C6 alkyl, specifically hydrogen; n is 0, 1, 2, or 3; each instance of R3 can independently be hydrogen, C1-C6 alkyl, phenoxy, C1-C6 alkoxy, halo, amino, C1-C6 alkylamino, di C1-C6 alkyl amino, imidazolyl, thiazolyl, isothiazolyl, thiadiazolyl, thienyl, furyl, pyrryl, naphthyl, Ph, halophenyl, C1-C6 alkyl Ph, or C1-C6 alkoxyphenyl. The preservative may be added to the emulsion after the emulsion is formed. The emulsion can be incorporated into a gypsum product such as gypsum board or gypsum wood fiber board. The gypsum product may be made by forming a slurry contg. gypsum, water, and the emulsion into a solid product. A method for improving the water resistance of a lignocellulosic composite product prepd. by mixing lignocellulosic material with a binder to form a mixt. and solidifying the mixt. in a selected configuration to form the composite product may include adding to the mixt. an emulsion as described above. A method was developed for the detn. of 7 thiophosphate compds. aspon [3244-90-4], dichlofenthion [97-17-6], famphur [52-85-7], fenitrothion [122-14-5], fonofos [944-22-9], phosmet [732-11-6], and thionazin [297-97-2] in wastewaters. The method development program consisted of a literature review; detn. of extn. efficiency for each compd. from water into CH2Cl2; development of a deactivated Florisil cleanup procedure; and detn. of suitable gas chromatog. (GC) anal. conditions. Extn. and cleanup procedures were developed to provide >=85% recoveries of these compds. from water. A packed column GC-AFD anal. procedure was also developed. The final method was applied to wastewater from a manufacturer of malathion [121-75-5] and to secondary effluent in order to det. the precision and accuracy of the method. The wastewaters were spiked with the 7 compds. at levels of 50 mg/L and 500 mg/L, resp. Recoveries for the 7 compds. were 85-89% at both concn. levels. Method detection limits (MDLs) for the 7 compds. in distd. water were 1-20 mg/L. MDLs in wastewaters may be higher due to interfering compds. 1369. Watanabe, T. (1996). Sampling Method for Determination of Pesticides in the Atmosphere Using Silica Gel Column. *Journal of pesticide science* 21: 147-152.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Sampling method was developed for analysis of various pesticides in the atmosphere using silica gel column (SEP-PAK cartridge) as adsorbent. Thirty eight pesticides were measured for the recoveries after fortification to silica gel, stability on silica gel under air passing, storage stabilities on silica gel and collection efficiencies of gaseous pesticides. The recoveries of pesticides fortified to silica gel column were over 96%. Fenthion and disulfoton on silica gel under air passing were unstable and it was presumed that they were decomposed by oxidation during the air passing. Edifenphos, simetryne, dimethylvinfos, tetrachlorvinfos and EPN were unstable in silica gel column at 25êC, then silica gel column was necessary to be kept under - 15êC until extraction after collection of the air. The collection efficiencies of butamifos, dimethoate, piperofos and phosmet were not satisfactory, i.e., 45-60%. However, the other 32 pesticides have useful efficiency.

Descriptors: Zea mays L.
Abstract: Herbicides are key products in sustaining agricultural production and, to minimize agro-environmental concerns regarding their use, continued assessment of their behavior under different management practices is required. Leaching and runoff losses of four herbicides applied preplant-incorporated (PPI) were evaluated in two tillage systems over a 3-year period (1989-1991). Scant leaching during the droughty 1991 growing season limited treatment evaluations to 2 years. Herbicides were applied at recommended rates (1.7 and 2.2 kg active ingredient (a.i.) ha superior - superior 1 to conventional tillage (CT) and mulch tillage (MT) corn (Zea mays L.) fields on Hagerstown silty clay loam (fine, mixed, mesic Typic Hapludalf). Tillage treatments were defined as moldboard plow-disk-harrow (CT) and single-disking (MT). During this study, CT followed 5 years of corn production in a comparable CT system on this site and, similarly, MT followed a 5-

year no-tillage (NT) system. Herbicides were applied preemergence (PRE) to CT and NT in the 5-year study and preplant-incorporated (PPI) in this study. Herbicide mobility in subsurface drainage was evaluated from herbicide mass transported to pan lysimeters installed 1.2 m deep. Surface drainage bosses of these chemicals were determined from residues in runoff collected with automated sampling and recording equipment. Leachate volumes were greater from MT than CT in 1989 and 1990 and exceeded all seasonal losses during the previous 5 years under NT management. Comparisons of total seasonal leachate discharged to pan lysimeters within and among studies and herbicide mass leached showed that timing of leachate-inducing precipitation relative to herbicide application was the key factor in regulating herbicide translocation. Herbicide mass transported through the root zone averaged from less than 0.1% to 0.9% of applied rates in CT and from 1.4% to 5.1% in MT. Leachate-availability of herbicide residues and extent of herbicide longevity in this soil under MT conditions were similar to previous findings under NT management. Despite these behavioral similarities for herbicides among tillages, herbicide mass discharged per unit of percolate was most often lower for MT compared with NT, particularly in early growing seasons of comparable precipitation. Thus, the PPI treatment in MT appeared to reduce leaching of these chemicals compared with PRE application in NT. Runoff losses of PPI herbicides ranged from 0.35% to 0.77% of applied rates in CT and front 0.13% to 0.28% in MT. Losses of PRE applied herbicides from NT averaged less than 0.1% of applied rates: maximum yearly losses ranged from 0.06% to 0.18%. Thus, the character of the disked, minimally tilled surface provided a level of impedance to runoff that was greater than achieved with the tilled surface on this 3 to 5%, slope, but less than previously obtained with an untilled, mulch-covered surface.

1373. Weaver, D. L. (1979). Diffusion-controlled mean reaction times in biological systems with elliptical symmetry. *Biophysical Chemistry* 10: 245-251.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The mean reaction (encounter or absorption) time is calculated in terms of the system size and reaction probability parameters for three-dimensional systems with diffusion-controlled dynamics and in which there is spherical, prolate spheroidal or oblate spheroidal geometry. Analytical and numerical comparisons are made among the three geometries. For completeness, similar results are derived for a two-dimensional elliptically symmetrical system, and the probability of non-absorption (or reaction) is found for a semi-infinite three-dimensional space with prolate or oblate spheroidal symmetry. http://www.sciencedirect.com/science/article/B6TFB-44GPJ1P-8F/2/a50b1690ba2024a2fe70887b64bcfa9a

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Soil water in the vadose zone and surface runoff water in a commercial apple orchard in an upland area of West Virginia (USA) were assessed for residues of pesticides normally applied for control of diseases, arthropod pests, and vole control. Water in the vadose zone was sampled at depths of 6, 12, 24, and 36 in. (0.15, 0.3, 0.6, and 0.9 m) with suction lysimeters from early spring to midfall for two consecutive years. Endrin was the only pesticide detected; it had been applied to the study site five times during the period of 1974 to 1981. None of the 17 pesticides applied under an Integrated Orchard Management program during this study were detected in water samples. Concentrations of endrin in soil water ranged from 0.1 to 13.2 ppb (mug). About 20% of all soil water samples within the orchard tested positive (\ 0.1 ppb) for this pesticide. Endrin was detected at all depths; however, the frequency of positive samples and levels of residues tended to decrease with dep

Twenty-four Agriculture and Agri-Food Canada, Soil Quality Evaluation Program (SQEP) benchmark soils and six intensively cropped southern Ontario soils exhibited similar small concns. of a few base-neutral and acid (BN&A) extractable industrial org. compds. (seldom>1 mg kg-1 dry wt), PCBs (<200 mg kg-1 dry wt) and organophosphorus pesticides (OPs). Fonofos, the only OP detected, was obsd. at concns. <100 mg kg-1 dry wt. Neutral and phenoxy acid herbicide analyses for 13 soils (seven SQEP and six intensively cropped) indicated infrequent detection of these compds. There was no detection of carbamate herbicides. In most soils, only trace amts. (<10 mg kg-1 dry wt) of OCs were obsd., but in one intensively cropped soil, DDT exceeded 70 mg kg-1 dry wt. A greater incidence of compds. such as a-chlordane, dieldrin, aldrin, and DDT in intensively cropped than in other soils is assumed to reflect increased use of these compds. for intensive crop prodn. Soils treated with sludge according to recommended practice exhibited minor increases in PAH, OC, and PCB concns. There is no risk to human health or the environment from industrial org. compds., except possibly DDT, in Canadian agricultural soils that have received no sludge or from PAHs, OCs, and PCBs in soils that have received southern Ontario sludges according to recommended practice. Abstract: In order to provide new insights into phylogenetic relationships among the neotropical taxa of Phyllanthus, 28 illustrations are provided of the pollen grains of 22 selected species studied from 11 sections of the subgenera represented in the neotropics. Special attention has been given to subgenus Conami because of its variability in pollen morphology: of eight species illustrated, the apertures are diploporate colpi in three species and pores in five species; exine ornamentation is vermiculate in two species and pilate in the other six species. The six species in the neotropical sections Pityrocladus and Microglochidion (subgenus Emblica) are characterized by prolate grains with an increased number of colpi (4-8). Of particular interest are species in which the pollen exine is clypeate (with exine shields); clypeate pollen grains are illustrated in two species of subgenus Xylophylla and in one species of section Cyclanthera that has unique exine shields with single central pila. The pollen of the one Brazilian phylloclade-bearing species illustrated (in section Choretropsis) has 3-colporate grains with reticulate exine, typical for subgenus Phyllanthus, and very different from the clypeate grains of the West Indian phylloclade-bearing species in section Xylophylla. This pollen evidence clearly demonstrates homoplasy in the origin of phylloclades in Phyllanthus. Pollen morphological data suggest that the neotropical taxa of Phyllanthus have arisen following colonization from Africa (subgenus Kirganelia) and Asia (subgenus Emblica). Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. The biological removal of ammonia and

butanal in contaminated air was investigated by using, respectively, a laboratory-scale filter and a scrubber-filter combination. It was shown that ammonia can be removed with an elimination efficiency of 83% at a volumetric load of 100 m3 m-2 h-1 with 4-16 ppm of ammonia. During the experiment percolates were analysed for nitrate, nitrite, ammonium and pH. It was found that the nitrification in the biofilter could deteriorate due to an inhibition of Nitrobacter species, when the free ammonia concentration was rising in the percolate. It should be easy to control such inhibition through periodic analysis of the liquid phase by using a filter-scrubber combination. Such a combination was studied for butanal removal. Butanal was removed with an elimination efficiency of 80% by a scrubber-filter combination at a volumetric load of 100 m3 m-2 h-1 and a high butanal input concentration. Mixing the filter material with CaCO3 and pH contro

Disability in Illnesses Related to Agricultural Use of Organophosphates (Ops) in California. *American journal of industrial medicine* 28: 257-274.
Chem Codes: Chemical of Concern: PSM Rejection Code: HUMAN HEALTH.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Organophosphate (OP)-related illness data reported to the Worker Health and Safety Branch (WH&S) at the California Department of Food and Agriculture (CDFA, now Cal-EPA) in the years 1984-1988 were examined. Eight hundred and seventy-eight cases with systemic illness and 199 cases of skin disease or eye injury were identified. Systemic cases were divided into two outcome groups: (1) "severe," disability and/or hospitalization days (n = 361), and (2) "mild," no disability or hospitalization days (n = 372). For the remainder (n = 145) or 16.5% of the cases, illness severity could not be determined. Using multiple logistic regression, independent predictors of "severe" illness were identified among the systemic cases. Workers coming in contact with OP residue on commodities or in the field ("exposed to residue" or ER) (OR = 4.6, 95% CI = 3.03-7.07) and mixer/loaders/applicators (MLA) (OR = 4.1, 95% CI = 2.726.07) were at significantly increased risk of severe illness when

1380. Weinhold, Paul A., Rounsifer, Mary Ellen, Charles, Linda, and Feldman, Douglas A. (1989). Characterization of cytosolic forms of CTP: choline-phosphate cytidylyltransferase in lung, isolated alveolar type II cells, A549 cell and Hep G2 cells. *Biochimica et Biophysica Acta (BBA) - Lipids and Lipid Metabolism* 1006: 299-310.
Chem Codes: Chemical of Concern: PSM Rejection Code: IN VITRO.

The subcellular forms of cytidylyltransferase (EC 2.7.7.15) in rat lung, rat liver, Hep G2 cells, A549 cells and alveolar Type II cells from adult rats were separated by glycerol density centrifugation. Cytosol prepared from lung, Hep G2 cells, A549 cells and alveolar Type II cells contained two forms of the enzyme. These species were identical to the L-Form and H-Form isolated previously from lung cytosol by gel filtration. Liver cytosol contained only the L-Form. Rapid treatment of Hep G2 cells with digitonin released all of the cytoplasmic cytidylyltransferase activity. The released activity was present in both H-Form and L-Form. The molecular weight of L-Form was determined from sedimentation coefficients and Stokes radius values to be 97 690 +/- 10 175. Thus, the L-Form appears to be a dimer of the Mr 45 000 catalytic subunit. The f f [degree sign] value of 1.5 indicated that the protein molecule has an axial ratio of 10, assuming a prolate ellipsoid shape. The estimated molecular weight of the H-Form was 284 000 +/- 25 000. The H-Form was dissociated into L-Form by incubation of cytosol at 37[degree sign]C. Triton X-100 (0.1%) and chlorpromazine (1.0 mM) also dissociated the H-Form into L-Form. Western blot analysis indicated that both forms contained the catalytic subunit. An increase in Mr 45 000 subunit coincided with the increase in cytidylyltransferase activity in L-Form, which resulted from the dissociated of H-Form. The L-Form was dependent on phospholipid for activity. The H-Form was active without lipid. Phosphatidylinositol was present in the H-Form isolated from Hep G2 cells. The phosphatidylinositol dispersed when the H-Form was dissociated into L-Form. Phosphatidylinositol and phosphatidylglycerol cause L-Form to aggregate into a form similar to H-Form. Phosphatidylcholine/oleic acid (1:1 molar ratio) and oleic acid also aggregated the L-Form. Phosphatidylcholine did not produce aggregation. We conclude that the H-Form is the active form of cytidylyltransferase in cytoplasm. The H-Form appears to be a lipoprotein consisting of an apoprotein (L-Form dimer of the Mr 45 000 subunit) complexed with lipids. A change in the relative distribution of H-Form and L-Form in cytosol would alter the cellular activity and thus may be important in the regulation of phosphatidylcholine synthesis. Photodecompn. curves are given for Gardona [22248-79-9] and cis-Gardona [22248-79-9] in sunlight and under UV light. Both the isomer and 2,4,5-trichlorophenacyl chloride [1201-42-9], the main metabolite, showed rapid degrdn. Methylnitrophos [122-14-5], cyanox [2636-26-2], and cyanoxone [61090-94-6] very highly volatile, but were resistant to hydrolysis in acid and neutral media. Phosalone [2310-17-0] was rapidly hydrolized in alk. medium, but was resistant to hydrolysis at pH ?6. In sunlight and UV light, phosalone decompd. slowly. Phthalophos [732-11-6] was rapidly converted by sunlight into its O analog [3735-33-9], hydroxymethylphthalimide [118-29-6], phthalimide [85-41-6], and a P-contg. unidentified compd. Sayfos [78-57-9] accumulation by the pea, grown from treated seed, depended on soil humidity and temp. The influence of soil characteristics and moisture on atrazine [1912-24-9], prometryne [7287-19-6], polytriazine [62655-79-2], and agelon [39464-88-5] persistence was also studied. Chem Codes: Chemical of Concern: PSM Rejection Code: REVIEW.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. The Colorado potato beetle, Leptinotarsa decemlineata (Say), is one of 13 insect and mite species in which development of insecticide resistance has become "critical." In this paper, we review methods for controlling this important agricultural pest while managing insecticide resistance. Many of these strategies were incorporated into an integrated pest management (IPM) program for northeastern potato growers and encapstilated in a knowledge-based expert system (PotatoES). Three years of field trails evaluating the IPM expert system's ability to act as a surrogate for a human specialist, its capability to manage Colorado potato beetle resistance development in experimental and commercial fields, and its impact on crop yields and production economics were conducted. Comparison of management recommendations made by PotatoES with those of a human IPM specialist demonstrated a high degree of agreement. Under experimental field conditions.

1384. Wen, H. Y. , Reischl, G. P., and Kasper, G. (1984). Bipolar diffusion charging of fibrous aerosol particles--II. charge and electrical mobility measurements on linear chain aggregates. *Journal of Aerosol Science* 15: 103-122.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Charge distributions on chain aggregates with thicknesses of less than 0.1 [mu]m and length-to-diameter ratios of 10 to several hundred were derived from measurements of electrical mobility distributions using a differential mobility analyzer (DMA), in combination with a condensation nuclei counter and an electrometer as particle detectors. The experiments are backed by measurements of chain size distributions with aerosol centrifuge and electron microscope, by DMA transfer function measurements, and by an investigation into the symmetry of the charging mechanism. Good agreement is found with the Boltzmann charge distribution when using a charging equivalent diameter DQE derived for conducting prolate spheroids.

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The following properties of Myrothecium cellulase were determined: diffusion coefficient, Dw, 20 = (5.6 +/- 0.1) x 10-7; sedimentation constant, Sw, 20 = (3.7 +/- 0.05) x 10-13; intrinsic viscosity, [[eta]] = 0.087 +/- 0.002 (assuming a nitrogen content of 16.0%). The molecular weight was

calculated to be 63,000 +/- 1500 (assuming a partial specific volume of 0.74 cc./g.). The frictional coefficient f/f0 was calculated to be 1.44 +/- 0.02. The hydrodynamically equivalent ellipsoid is prolate with an axial ratio variously estimated as between about five and ten.

1386. Who Genev Switzerland (Pesticide Residues in Food. *Who tech. Rep. Ser. 612: 35pp. 1977 (36 references).*
Chem Codes: Chemical of Concern: PSM Rejection Code: HUMAN HEALTH.

ABSTRACT: PESTAB. Possible hazards to man arising from residues of pesticides present in foods were evaluated. Consideration was given to fenitrothion, carbaryl, diquat, and phosalone in relation to residue data, and chlordimeform and leptophos in light of potential toxicological hazards. Specific problems considered included the aliesterase- inhibiting compounds, organophosphorus insecticides which inhibit aliesterase activity in the liver and serum at concentrations lower than those that inhibit cholinesterase. Attention was also given to reversible cholinesterase inhibition, suspended production of chlordimeform, and the toxicological problems associated with leptophos. Potential hazards associated with leptophos were seen as two-fold: occupational or accidental exposure of individuals to high doses for short periods, and long-term low level exposure and possible build-up of the toxicant to threshold levels leading to ataxia. The evaluation of available data for the purpose of establishing acceptable daily intakes were reported for acephate, dialifor, edifenphos, methamidophos, phosmet, carbofuran, formetanate, methomyl, pirimicarb, bioresmethrin, cartap, chlormequat and choline chloride, maleic hydrazide, and propargite. Pesticides which had been previously evaluated included carbophenothion, pirimiphos-methyl, thiometon, carbendazim, captafol, diphenylamine, dodine, and paraquat.

Citations: Rath, M; EP 1163904 A 2001 The invention discloses a process for the prepn. and activation of a substance and a means for producing the activated substance. In particular, the invention discloses a method for treating a disease in a subject in need of such treatment, comprising administering a substance or active agent which comprises one or more components which have been agitated such that a harmonic of 20-50 Hz has been produced, in an amt. effective to treat the disease, with the proviso that the disease is not an airway disorder. <u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: PATENT.

Database: CAPLUS
Accession Number: AN 2005:141200
Chemical Abstracts Number: CAN 142:254568
Section Code: 1-6
Section Title: Pharmacology
Coden: PIXXD2
Index Terms: Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) ((oxydi-2,1-ethanediyl)bis[cocoalkyldimethyl, chlorides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Zeolites Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (Ag; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Zeolites Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (AgCu; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Zeolites Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (AgZn; methods and compns. for increasing efficacy of biol. active

ingredients such as antitumor agents); Surfactants (Armul, Berol, Emcol, Emphos, Emulgator, Emulsogen, Flomo, Pluraflo E4A, Surflo, Toximul, Trycol, Tryfac; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Solvent naphtha (Arom. 100, Hi-Sol 15, Lubrizol 544; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Proteins Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (Bacillus thuringiensis kurstaki; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (Calendula officinalis; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Balsams Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (Canadian; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (Chenopodium; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Isoalkanes Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (C11-12; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Alcohols Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (C11-15, ethoxylated, compds. with iodine; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Alcohols Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (C11-15-secondary, ethoxylated, Tergitol 15-S-20; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Isoalkanes Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (C12-14; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Alcohols Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (C12-15; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (C12-18-alkyltrimethyl, chlorides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Sulfonic acids Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (C20-30-alkanesulfonic, zinc salts; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Alcohols Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (C4-12; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Alkanes Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (C5-20; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Alcohols Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (C6-12; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Diglycerides; Glycerides; Monoglycerides Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (C8-10 monoglycerides and diglycerides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Alcohols Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (C8-10; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Polysiloxanes Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (DB-110A, Y-30; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Solvents (Dowanol, Espesol; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Pheromones Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (German cockroach; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Bacillus thuringiensis kurstaki (HD-1; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Soaps Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (Ivory Snow; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fats and Glyceridic oils Role: PAC (Pharmacological activity), THU

(Therapeutic use), BIOL (Biological study), USES (Uses)   (Japan wax; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Sarcoma   (Kaposi's; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Gene Role: BSU (Biological study, unclassified), BIOL (Biological study)   (MDR, Arabidopsis thaliana; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Polyurethanes Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses)   (Macroplast; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses)   (Melaleuca alternifolia; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Stabilizing agents   (Nuostabe V 1913; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Hydrocarbon oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (Orchex 796; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Balsams Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses)   (Peru; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses)   (Ruta graveolens, Rutaceae; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses)   (Siberian fir; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Emulsifying agents   (Sponto; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Antimicrobial agents (Sterilix; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Named reagents and solutions Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses)   (Stoddard; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Lymphoproliferative disorders (Waldenstrom's macroglobulinemia; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Kidney   (Wilms'; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Urethanes Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (adhesives; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Immunostimulants   (adjuvants, T-Mulz; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Flours and Meals   (alfalfa; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Amines; Petroleum resins Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses)   (aliph.; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Helleborus; Schoenocaulon   (alkaloids; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Sulfonic acids Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses)   (alkanesulfonic, potassium salts; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Surfactants   (alkanolamides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses)   (alkenyldimethylethyl, bromides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds; Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses)   (alkyl(dichlorobenzyl)dimethyl, chlorides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (alkyl[(dichlorophenyl)methyl]dimethyl, chlorides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Polyoxyalkylenes Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (alkylaryl ethers; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (alkylbenzyldimethyl, alkylamines; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (alkylbenzyldimethyl, chlorides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (alkyldi(hydroxyethyl)methyl, chlorides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (alkyldimethyl(dimethylbenzyl), chlorides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (alkyldimethyl(ethylbenzyl), chlorides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (alkyldimethyl(ethylbenzyl), cyclohexylsulfamtes; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (alkyldimethyl(hydroxyoxopyranylmethyl), chlorides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (alkyldimethyl(isopropylbenzyl), chlorides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (alkyldimethyl(isopropylphenyl), chlorides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds; Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (alkyldimethylethyl, bromides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (alkyldimethylethylbenzyl, cyclohexylsulfamates; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (alkyldimethylethylbenzyl, cyclohexylsulfonates; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (alkyltrimethyl, bromides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (alkyltrimethyl, chlorides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Waxes Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (ambergris; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fatty acids Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (amine salts; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Caseins Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (ammonium complexes; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (anise; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Antitumor agents (antibiotic; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Cytotoxic agents (antimetabolites; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Antibiotics; Drug resistance (antitumor; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Petroleum Role: PAC (Pharmacological activity), THU

(Therapeutic use), BIOL (Biological study), USES (Uses) (arom., alkylated; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Straw (barley; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (bay; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (benzyl(hydrogenated tallow alkyl)dimethyl, bentonite salts; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (benzyl-C12-14-alkyldimethyl; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (benzyl-C12-16-alkyldimethyl, chlorides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (benzyl-C12-18-alkyldimethyl, salts with 1,2-benzisothiazol-3(2H)-one 1,1-dioxide (1:1); methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (benzylcoco alkylbis(hydroxyethyl), chlorides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (bergamot; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (bis(hydrogenated tallow alkyl)dimethyl, Me sulfates; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Prunus amygdalus (bitter almond; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Slags (blast-furnace; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Linseed oil Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (boiled; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fats and Glyceridic oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (bone oil; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (cade; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Pigments (cadmium yellow; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (cajuput; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Shale Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (calcareous; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Caseins Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (calcium complexes; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (camphor; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Feed (canary seed; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Waxes Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (candle; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Syrups (cane; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Gelatins Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (capsules; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Head and Neck; Head and Neck (carcinoma; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Feed (cat food;

methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Milk substitutes (cattle; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (cedar leaf; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (cedarwood; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Uterus (cervix; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (chamomile, German; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Perfumes (cherry fragrance oil 493; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Paraffin waxes Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (chloro; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Carcinoma; Chorion (choriocarcinoma; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (cinnamon; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (citronella; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Cellulose pulp (citrus; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (citrus; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (clove; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Phenols Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (coal tar; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Naphtha Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (coal; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Amines Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (coco alkyl, compds. with tetrachlorophenol (1:1); methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Amides Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (coco, N-(hydroxyethyl); methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fatty acids Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (coco, cadmium salts; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fatty acids Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (coco, diethylamine salts; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Theobroma cacao (cocoa shells; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Amine oxides Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (cocoalkyldimethyl; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Intestine (colon; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Bentonite Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (compd. with dimethyldioctadecylammonium chloride; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Bakery products (cookies; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Naphthenic acids; Resin acids Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (copper salts; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Flours and Meals (corn, hearts; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Flours and Meals (corn; methods and compns. for increasing efficacy of biol.

active ingredients such as antitumor agents); Fatty acids Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (cottonseed-oil, Me esters; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Flours and Meals (cottonseed; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Avena sativa; Triticum aestivum (cracked; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Bread (crumb; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Syzygium aromaticum (crushed; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (cubeb; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (di(alkyloxypropyl)dimethyl, chlorides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (dialkylbenzylmethyl, chlorides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (dialkyldimethyl, chlorides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (dialkyldimethyl, polynaphthylamines; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Quaternary ammonium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (dicoco alkyldimethyl, chlorides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fatty acids Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (dimer acids; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Coal tar Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (distillate, heavy oils; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Coal tar Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (distillate, upper; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Petroleum products (distillates, C12-30-arom.; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Petroleum products (distillates, KM spray oil; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Petroleum products (distillates, aliph.; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Petroleum products (distillates, arom.; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Petroleum products (distillates, hydrotreated light paraffinic; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Petroleum products (distillates, refined; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Petroleum products (distillates, solvent-refined light paraffinic; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Petroleum products (distillates; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Lime Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (dolomitic; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Blood (dried; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); High throughput screening (drug; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Nicotiana tabacum (dust; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Uterus (endometrium, adenocarcinoma; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Linseed oil Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (epoxidized; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Myeloproliferative disorders (essential thrombocythemia; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fatty acids Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (esters; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Monoglycerides Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (ethoxylated coco; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Lanolin Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (ethoxylated, acetate; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Lanolin Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (ethoxylated; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (eucalyptus; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Citrus (ext. and meal; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Allium cepa; Glycine max; Juniperus communis; Malt; Myrica cerifera (ext.; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Calendula officinalis; Gland; Lavandula; Lonchocarpus; Salvia; Tanacetum (exts.; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Alcohols Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (fatty, C4-16; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Alcohols Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (fatty; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fatty acids Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (fish-oil, potassium salts; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fats and Glyceridic oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (fish; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Zea mays (flour and meal, hearts; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Cottonseed; Glycine max; Secale cereale; Zea mays (flour and meal; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Wood (flour; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Polyesters Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (foam, UL-94 HF1 listed; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Mycosis (fungoides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Repellents (game; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (geranium; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Vitis vinifera (grape pomace; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Pseudotsuga menziesii (ground bark; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Oryza sativa (ground hulls; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Sesamum indicum (ground plant; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Avena sativa; Corncob (ground; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Coffea (grounds; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Wood (hard, oil; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Carcinoma; Carcinoma (head and neck; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Naphtha Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (heavy arom.; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Drug screening (high throughput; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Coal tar pitch (high-temp.; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents);

Prunus amygdalus (hulls, shells; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Glycine max; Oryza sativa (hulls; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Neoplasm (humoral hypercalcemia of malignancy; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Resin acids Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (hydrogenated, Me esters; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Castor oil; Rosin; Soybean oil Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (hydrogenated; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Food analysis (hydrolyzed corn-contg.; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Syrups (hydrolyzed starch; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Zea mays (hydrolyzed; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Paraffin waxes Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (hydrotreated; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Pancreatic islet of Langerhans (insulinoma; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Syrups (invert; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Antibacterial agents (iodophors; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Pigments (iron oxide; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (jasmine; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Paints (latex; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (lavender; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Naphthenic acids Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (lead salts; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Eucalyptus; Mentha pulegium (leaves; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (lemon; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (lemongrass; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Skin (lesion; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Naphtha Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (light arom.; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (lime; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Dyes (liq., Green M; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Capsicum annuum annuum (longum group, paprika; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Paraffin oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (low-mol.-wt.; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fats and Glyceridic oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (margosa; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Beta vulgaris saccharifera; Fish; Meat; Medicago sativa (meal; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Flours and Meals (meat meal; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Myocastor coypus (meat; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fats and Glyceridic oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES

(Uses) (menhaden; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Naphthenic acids Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (mercury salts; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Acacia; Acute lymphocytic leukemia; Adrenal cortex; Agrobacterium tumefaciens; Agrobacterium vitis; Agrotis segetum granulovirus; Alkylating agents; Allium cepa; Allium sativum; Ampelomyces quisqualis; Anthracene oil; Antibiotic resistance; Apparatus; Arabidopsis thaliana; Arachis hypogaea; Aschersonia aleyrodis; Autographa californica nucleopolyhedrovirus; Avena sativa; Bacillus amyloliquefaciens; Bacillus cereus; Bacillus sphaericus; Bacillus subtilis; Bacillus thuringiensis; Bacillus thuringiensis darmstadiensis; Bacillus thuringiensis morrisoni; Beeswax; Bladder; Bone meal; Brain; Bran; Burkholderia cepacia; Capsicum; Caramel; Carcinoid; Cheese; Chronic lymphocytic leukemia; Chronic myeloid leukemia; Cinnamon; Colloids; Combination chemotherapy; Cork; Corncob; Cottonseed meal; Creosote; Cytotoxic agents; Daucus carota; Desmodium; Drug delivery systems; Drug screening; Drugs; Dyes; Egg; Esophagus; Filter paper; Flours and Meals; Fumigants; Fungicides; Gentiana; Glues; Gossypium hirsutum; Hairy cell leukemia; Helicoverpa zea; Helicoverpa zea nucleopolyhedrovirus; Herbicides; Hodgkin's disease; Honey; Human; Insecticides; Jet aircraft fuel; Liliopsida; Lung; Lymantria dispar nucleopolyhedrovirus; Magnoliopsida; Mammary gland; Matricaria recutita; Meat; Medicago sativa; Melanoma; Mentha piperita; Milk; Mint; Molasses; Multiple myeloma; Neodiprion lecontii nucleopolyhedrovirus; Neodiprion sertifer; Nicotiana tabacum; Nosema locustae; Oatmeal; Odor and Odorous substances; Orgyia pseudotsugata nucleopolyhedrovirus; Oryza sativa; Ovary; Paecilomyces fumoso-roseus; Paecilomyces lilacinus; Paenibacillus lentimorbus; Paints; Paper; Paperboard; Peanut butter; Phlebia gigantea; Phlebiopsis gigantea; Phytophthora palmivora; Piper nigrum; Polycythemia vera; Propellants; Prostate gland; Pseudomonas chlororaphis; Pseudomonas fluorescens; Pseudomonas syringae; Puccinia canaliculata; Quassia; Quillaja; Rabbit calicivirus; Raisin; Rhizobium leguminosarum; Rhizobium leguminosarum phaseoli; Rosmarinus officinalis; Sawdust; Seaweed; Sinorhizobium meliloti; Skin; Sludges; Solanum tuberosum; Sorghum bicolor; Soybean meal; Sphagnum; Spodoptera exigua nucleopolyhedrovirus; Staphylococcus aureus; Stomach; Streptomyces griseoviridis; Tar oils; Testis; Thickening agents; Thymus; Tomato mosaic virus; Trichoderma harzianum; Trichoderma polysporum; Trigonella foenum-graecum; Triticum aestivum; Urogenital system; Verticillium lecanii; Wheat flour; Whey; Wool; Xanthomonas campestris poannua; Yeast; Zea mays (methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Amino acids; Aminoglycosides; Androgens; Asbestos; Asphalt; Bentonite; Canola oil; Carbon black; Caseins; Castor oil; Chlorinated natural rubber; Coal tar; Coconut oil; Cod liver oil; Collagens; Corn oil; Corticosteroids; Cottonseed oil; Creosote oil; Cytokinins; Diatomite; Epoxy resins; Essential oils; Feldspar-group minerals; Fertilizers; Gasoline; Gelatins; Gibberellins; Glycopeptides; Granite; Growth regulators; Humic acids; Jojoba oil; Kaolin; Kerosene; Lard; Ligroine; Lime; Linseed oil; Macrolides; Mica-group minerals; Naphthenic acids; Naphthenic oils; Natural products; Nitrile rubber; Olive oil; Palm oil; Paraffin oils; Paraffin waxes; Peanut oil; Perlite; Petrolatum; Petroleum hydrocarbons; Petroleum resins; Petroleum spirits; Phenols; Phosphoproteins; Plastics; Polyamide fibers; Polyamides; Polyenes; Polyoxyalkylenes; Polyvinyl butyrals; Progestogens; Protein hydrolyzates; Pumice; Pyrethrins; Rape oil; Resins; Rosin; Rubber; Safflower oil; Sand; Saponins; Shale; Shellac; Silica gel; Soapstone; Soybean oil; Tall oil; Tallow; Tetracyclines; Tung oil; Turpentine; Waxes; Wood tar; Zeins Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fats and Glyceridic oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (mink; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Onium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (morpholinium, 4-Et, ethylsulfates; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Onium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (morpholinium, 4-ethyl-4-soya alkyl, Et sulfates; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Onium compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (morpholinium, alkylmethyl, sulfates; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Anagrapha falcifera (multi-nuclear polyhedrosis virus; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Skin (mycosis fungoides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Abies (needle oil; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Nerve (neuroblastoma; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Chloramines Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (nitrogen mustards; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fuel oil (no. 1, no. 2, no. 4, no. 6; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Diesel fuel (no. 2; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Lymphoma (non-Hodgkin's; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Surfactants (nonionic; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Meat (nutria; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Aloe barbadensis; Lavandula hybrida (oil; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Coal tar Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (oil; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Resins Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (oleoresins, capsicum; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Resins Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (olibanum; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (orange, sweet; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Bone; Sarcoma (osteosarcoma; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Solvents (oxygenated; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Citrus limon (peel oil; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (pennyroyal, Hedeoma pulegioides; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (pepper, Piper nigrum berry; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (peppermint; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Tar Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (pine, oil; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Tar oils (pine; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils; Tar Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (pine; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Rosin Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (polymd.; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Linseed oil Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (polymer with dicyclopentadiene; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Linseed oil Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (polymer with maleic anhydride and tung oil, Kelsol 5134; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Vinyl compounds Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (polymers; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Malus pumila (pomace; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Feed (poultry; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Gelatins Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (powd.; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Beta vulgaris (powder; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Carcinoma (pulmonary small-cell; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Citrus sinensis; Orange (pulp; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Bombyx mori (pupae; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Derris (resins; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Antitumor agents (resistance to; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Sarcoma (rhabdomyosarcoma; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Cucurbita foetidissima (root powder; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (rosemary; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (rosin; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Flours and Meals (rye; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Naphthenic acids Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (salts, compd. with dodecyldimethylbenzylammonium; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Resin acids Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (salts, tributyltin salt; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Sulfonic acids Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (salts; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (sassafras; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Algae (sea, ext.; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Weed (seed oil; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Panicum (seed; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fats and Glyceridic oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (sesame; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fertilizers Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (sewage sludge; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Carya illinoinensis (shell, flour; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Egg (shell; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Juglans regia (shells, ground; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Arachis hypogaea; Clam; Oyster (shells; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Aerogels (silica; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Lung (small-cell carcinoma; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Coconut oil Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (soap; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Caseins Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (sodium complexes; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Polyphosphoric acids; Sulfonic acids Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (sodium salts; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Soaps Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (sodium tallow; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Animal tissue (soft, neoplasm, sarcoma; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Sarcoma (soft-tissue; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Amines Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (soya alkyl, ethoxylated; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fatty acids Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (soya, Me esters; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fatty acids Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (soya, tertiary amine salts; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Flours and Meals (soybean; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Proteins Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (soybean; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (spearmint; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fats and Glyceridic oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (sperm oil; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Gliocladium catenulatum; Paenibacillus popilliae; Phlebiopsis gigantea (spores; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Hordeum vulgare (straw; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Bacillus thuringiensis san diego (subsp San Diego; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Cod liver oil Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (sulfonated; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Petroleum Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (sulfurized; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Helianthus annuus (sunflower seed; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Seed (sunflower; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fatty acids Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (tall-oil, copper salts; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fatty acids Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (tall-oil, potassium salts; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fatty acids Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (tall-oil; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Soaps Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (tallow; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (thyme, Thymus vulgaris; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Antifouling agents (tin-contg. acrylic polymer contg.; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Acrylic polymers Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (tin-contg.; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Naphthenic acids Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (tributyltin salts; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Carcinoma (uterine endometrial adenocarcinoma; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fats and Glyceridic oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (vegetable, hydrogenated; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fats and Glyceridic oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological

study), USES (Uses) (vegetable, methylated; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fats and Glyceridic oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (vegetable; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Alkaloids Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (vinca; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Juglans regia (walnut flour; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Dyes (water-sol.; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Glycerides Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (wheat germ-oil; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Fats and Glyceridic oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (wheat germ; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Essential oils Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (wintergreen; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); Creosote (wood; methods and compns. for increasing efficacy of biol. active ingredients such as antit
CAS Registry Numbers: 92-52-4D (1,1'-Biphenyl) Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (Aroclor; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); 125695-78-5 Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (Isomate LBAM; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); 106998-35-0 Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (Isomate OFM; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); 11104-05-5 Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (Luretape; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); 9003-28-5 Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (Polyvis O-SH; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); 60568-05-0 Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (Xyligen B; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); 9000-69-5 (Pectin) Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (citrus; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); 7631-86-9 (Silica) Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (cryst.-fused; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); 64529-56-2 Role: PAC (Pharmacological activity), THU (Therapeutic use), BIOL (Biological study), USES (Uses) (ebuzin,tycor; methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); 9001-77-8D Role: BSU (Biological study, unclassified), BIOL (Biological study) (methods and compns. for increasing efficacy of biol. active ingredients such as antitumor agents); 50-00-0 (Formaldehyde);

Priority Application Country: US
Priority Application Number: 2002-418803
Priority Application Date: 20021016 The invention provides methods and compns. for modulating the sensitivity of cells to cytotoxic compds. and other active agents. In accordance with the invention, compns. are provided comprising combinations of ectophosphatase inhibitors and active agents. Active agents include antibiotics, fungicides, herbicides, insecticides, chemotherapeutic agents, and plant growth regulators. By increasing the efficacy of active agents, the invention allows use of compns. with lowered concns. of active ingredients. [on SciFinder (R)]

1389. Wing, K. D., Glickman, A. H., and Casida, J. E. (1984). Phosphorothiolate Pesticides and Related

Compounds: Oxidative Bioactivation and Aging of the Inhibited Acetylcholinesterase. *Pestic biochem physiol* 21: 22-30.
Chem Codes: Chemical of Concern: PSM Rejection Code: IN VITRO.

ABSTRACT: HEEP COPYRIGHT: BIOL ABS. Several phosphorothiolates with a C2 to C6 S-alkyl substituent (i.e., ethyl, n-propyl, isopropyl, n-butyl, t-butyl, n-pentyl, or cyclohexyl) undergo microsomal oxidase activation to more potent acetylcholinesterase (AChE) inhibitors. Profenofos is activated by both mouse liver and house fly abdomen microsomes. The phosphorothiolates examined having S-methyl, S-benyzl, S-phenyl and a variety of other thiol substituents and the phosphoramidothiolates were not converted to more potent AChE inhibitors. The microsomal oxidase system cleaves (|)-profenofos predominantly at the P-S-propyl linkage probably via initial sulfoxidation. (-)-Profenofos and O,S-diethyl O-phenyl phosphorothioate undergo in vivo oxidative activation as evidenced by lessened chick brain AChE inhibition after pretreatment with piperonyl butoxide. AChE inhibited in vitro by several bioactivated phoshporothiolates quickly becomes refractory to oxime reactivation, i.e., it undergoes aging. The toxicological properties of some S-propyl S-butyl, and related phosphorothiolates are determined in part by their bioactivation and AChE-aging reactions.

ABSTRACT: Benzene is an important carcinogenic substance used in many industrial processes. Inhalation of this substance can cause both acute and chronic toxicity. In this study, monitoring of benzene exposure by high-performance liquid chromatography (HPLC) for urine trans, trans-muconic acid (ttMA) determination was adapted. We described a new adapted sensitive and specific HPLC method. We mixed 0.5 mL of urine sample with 2 mL of Tris Buffer containing vanillic acid as internal standard (IS) and percolate this through a preconditioned ion-exchange column. After rinsing the column with phosphoric acid solution, acetate buffer, and deionized water, we eluated the analytes with 2 mL of an equivolume solution of 1.5 mol/L sodium chloride and methanol. Of this, 10 microliter was injected into the HPLC column. The mobile phase consisted of, per liter, 10 ml of acetic acid, 100 ml of methanol, and 5 mmol/L sodium acetate. The flow rate was started at 1.2 ml/min. The ttMA and IS were detected at 4.2 to 4.4 and 12.6-13.3 minutes, respectively. The lowest detection limit was 0.05 mg/L.

1393. Wolfberg, A., Kahanovich, Y., Avron, M., and Nissenbaum, A. (1980). Movement of heavy metals into a shallow aquifer by leakage from sewage oxidation ponds. *Water Research* 14: 675-679.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

The concentrations of Mn, Ni, Cu, Cd and Cr were measured in a shallow perched groundwater aquifer which underlies the Dan Region Sewage Reclamation Project (Israel). The contribution of effluents to the groundwaters has been evaluated on the basis of chloride concentration. Groundwater which are estimated to contain more than 60% effluents showed a hundred-fold decrease in Cu and Mn at a distance of 650 m away from the ponds, as compared with the near ponds samples. Ni and Cd showed only a small decrease in concentration over a distance of 150 m, and then stayed constant. The concentrations of Cu and particularly of Mn in the groundwaters near the oxidation ponds is equivalent to or greater than in the ponds themselves. It is suggested that Cu and Mn are mobilized from the precipitated sludge into the interstitial waters. They percolate into the groundwater near the ponds and then are precipitated by increasing aeration during the movement of the water away from the pond area. Cd and Ni form stable soluble organic chelates which are only slightly removed by interaction with the sandy soil of the aquifer.

Wine samples were applied to solid phase extn. cartridges (C-18, octadecyl), and pesticides were eluted with Et acetate. The reduced solvent exts. were subsequently screened and analyzed by gas chromatog.-mass spectrometry using full scan or selected ion monitoring. Target and qualifier ions and retention times were used to screen, confirm, and det. recoveries of 48 common pesticides. Various parameters including pesticide spike concns., wine type (red and white), and salt addn. prior to extn. were compared and evaluated for highest extn. efficiencies and optimal sensitivity in spiked wine samples. Suitable recoveries to most pesticides at the 0.01 and 0.10 mg/L fortifications were obtained by adding sodium chloride prior to extn. and Et acetate elution. These findings confirm that this is a fast and effective method for identifying several types of pesticides in wines. [on SciFinder (R)] 0002-9254 pesticide/ residue/ wine/ analysis

Pesticides were extd. from the sample using acetonitrile/water satd. with salts, followed by solid-phase dispersive cleanup, and analyzed by capillary gas chromatog. with electron ionization mass spectrometry in selective ion monitoring mode (GC-MS/SIM) and flame photometric detection (GC-FPD) in phosphorus mode. The detection limits for most of the pesticides were 0.025-0.05 mg/g using GC-FPD but were analyte-dependent for GC-MS/SIM, ranging from 0.005 to 0.50 mg/g. Quantitation was detd. from 0.050 to 5.0 mg/g with r2 > 0.99 for a majority of the pesticides using both detectors. Recovery studies were performed by fortifying the dried ground ginseng root samples to concns. of 0.025, 0.1, and 1.0 mg/g, resulting in recoveries of >90% for most pesticides by GC-FPD. Lower (<70%) and higher (>120%) recoveries were most likely from complications of pesticide lability or volatility, matrix interference, or inefficient desorption from the solid-phase sorbents. There was difficulty in analyzing the ginseng samples for the OPs using GC-MS at the lower fortification levels for some of the OPs due to lack of confirmation. GC-FPD and GC-MS/SIM complement each other in detecting the OPs in dried ground ginseng root samples. This procedure was shown to be effective and was applied to the anal. of OPs in ginseng root samples. One particular sample, a ground and dried American ginseng (Panax quinquefolius) root sample, was found to contain diazinon quantified at approx. 25 mg/kg by external calibration using matrix-matched stds. or std. addn. using both detectors. The advantage of using both detectors is that confirmation can be achieved using GC-MS, whereas the use of a megabore column in GC-FPD can be used to quantitate some of the nonpolar OPs without the use of matrix-matched stds. or std. addn. Three GC injections were required to analyze and identify organophosphate, organohalogen, and organonitrogen pesticides. The pesticides were identified by the retention times of peaks of the target ion and qualifier-to-target ion ratios. GC detection limits for most of the pesticides were 5-10 ng/mL, and linearity was detd. from 50 to 5000 ng/mL. Fortification studies were performed at 10 ng/mL for three malt beverages that differ in properties such as alc. content, solids, and appearance. The recoveries from the three malt beverages were greater than 70% for 85 of the 142 pesticides (including isomers) studied. The data showed that the different malt beverage matrixes had no significant effect on the recoveries. This method was then applied to the screening and anal. of malt beverages for pesticides, resulting in the detection of the insecticide carbaryl and the fungicide dimethomorph in real samples. The study indicates that pesticide levels in malt beverages are significantly lower than the tolerance levels set by the United States Environmental Protection Agency for malt beverage starting ingredients. The use of the extn./cleanup procedure and anal. by GC-MS(SIM) proved effective in screening malt beverages for a wide variety of pesticides. Citations: 24) Tadeo, J; Food Analysis by HPLC, 2nd ed 2000, 693 A method was developed to det. pesticides in wines. The pesticides were extd. from the wine using solid-phase extn. on a polymeric cartridge, and the Co-extractives were removed with an aminopropyl-MgSO4 cartridge. Anal. was performed using capillary gas chromatog. with electron impact mass spectrometric detection in selective ion monitoring mode (GC-MSD/SIM). Three injections are required to analyze all 153 organohalogen, organonitrogen, organophosphate, and organosulfur pesticides and residues. Pesticides were confirmed by retention times of the target ions and 3 qualifier-to-target ion ratios. Detection limits for most of the pesticides were < 0.005 mg/L, and quantitation was detd. from .apprx. 0.01 to 5 mg/L. Spike recoveries were performed by fortifying red and white wines at 0.01 and 0.10 mg/L. At the 0.01 ppm level, the spike recoveries were > 70% for 116 and 124 pesticides (out of 153) in red and white wines, resp., whereas at the higher spike concn. of 0.10 mg/L, the recoveries were > 70% for 123 and 128 pesticides in red and white wines, resp. The recoveries of < 70% were most likely from pesticide polarity or lability, resulting in the inefficient adsorption of the pesticide to the polymeric sorbent, ineffective elution of the pesticide from the sorbent, or thermal degrdn. of the pesticide under GC-MSD conditions. ISSN: 0010-3624
Abstract: Alabama's broiler chicken (Gallus gallus) industry produces large amounts of waste, which are disposed of by application to crop and pasture land. Land application of litter (manure and bedding) from broiler production can lead to contamination from losses of nutrients accumulated in soil. A study was conducted on 2 and 4% slopes from 1991 to 1993 at Belle Mina,

Alabama, to determine the effects of broiler litter (BL) on soil elemental concentrations and nitrate leaching under a corn (Zea mays L.) - winter rye (Secale coreale L.) cropping system amended with either: 1) 9 mg midline dot ha superior - superior 1 of BL, 2) 18 mg midline dot ha superior - superior 1 of BL, or 3) commercial fertilizer (F) at a recommended rate. Soil was sampled to 100 cm prior to corn planting and subsequent to corn harvest. Soil leachate samples were collected biweekly with wick lysimeters installed at a depth of 100 cm. Litter applications increased concentrations of soil organic carbon (C), extractable phosphorus (P), potassium (K), calcium (Ca), magnesium (Mg), copper (Cu) and zinc (Zn). Post harvest soil sampling indicated leaching of soil nitrate that was generally highest under BL18. Soil electrical conductivity measurements were highest under BL18, but values were not in the range considered detrimental to crops. Nitrate-N (NO inferior 3-N) concentrations measured in soil percolate at 1-m depth on the 2% slope were higher under F than litter treatments. Both the F and BL18 treatments produced some NO inferior 3-N concentrations above the primary drinking water standard, but averaged only 8.3 and 4.8 mg midline dot L superior - superior 1, respectively. The BL9 treatment consistently remained under 10 mg NO inferior 3-N midline dot L superior - superior 1 with a mean concentration of 1.3 mg midline dot L superior - superior 1. Overall, litter applied a 9 mg midline dot ha superior - superior 1 produced agronomic results comparable to F and appeared to be the optimal rate of application under the conditions of this study.

1401. Wright, A. Kent (1976). A study of rhodopsin-detergent micelles by transient electric birefringence. *Biophysical Chemistry* 4: 199-202.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The hydrodynaimc method of transient electric birefringence has been used to study bovine rhodopsin solubilized in two detergents, 0.02% Ammonyx LO and 0.045% digitonin. All measurements are interpreted as the sum of two exponentials by which the relaxation times yield the rotary diffusion coefficients for ellipsoids of revolution. The semi-major and minor axes for prolate ellipsoid models have been calculated and their axial ratio, 6.8, in both detergents, is in line with recent reports on the structure of rhodopsin. Studies on bleached rhodopsin showed a large increase in axial ratio in 0.02% Ammonyx LO.

Chem Codes : Chemical of Concern: PSM Rejection Code: CHEM METHODS.

A molecular dynamics (MD) simulation study of a dodecylphosphocholine (DPC) micelle in water is presented. This system contains 60 DPC molecules in 5294 water molecules. The structure, shape, hydrocarbon chain fluidity, the hydration of the head group and the hydrocarbon chain, and the dynamics of the micelle were analyzed from the 1.2 ns constant pressure MD simulation. The micelle was found to be slightly prolate, with the ratio of the moments of inertia 1:24:1.11:1. The penetration of water into the interior of the micelle is limited. The interaction of water with the micelle mainly comes from the head group, and the modes of interaction with the positively charged choline group and the negatively charged phosphate group can be deciphered from the radial distribution functions between these groups and both the hydrogen and the oxygen atoms of water. From the ratio of the trans/gauche conformers on the hydrocarbon chain, and the density distribution of the various carbons with respect to the center of the mass of the micelle, the conformational properties of the hydrocarbon chains have been analyzed. The dynamics of the micelle was probed by the trans-gauche conformational transition rates and from the time correlation function of the C-H bonds. From the latter, the order parameters and the correlation times for the internal motions have been obtained. These parameters were found to be, for the most part, in excellent agreement with those obtained from NMR relaxation. This test employs microtitration techniques and photometric anal. with numerical readout. These data are integrated into the computerized data processing program Statistical Anal. System to obtain genotoxicity and toxicity results of a chem. or chem. mixt. within 16 h. In order to test the applicability of the new system, the genotoxicity and toxicity of 22 pesticides were studied. A 2-sample t-test was employed to det. the level of significance. Nine of the pesticides were found to induce the SOS response in Escherichia coli cells. Their relative degrees of induction based on SOS inducing potency values are as follows: captafol < captan < folpet < dinoseb < ferbam < linuron < alachlor < phosmet < cacodylic acid. The addn. of rat liver S9 mix does not transform the nongenotoxic pesticides tested into genotoxic forms but significantly decreases the inducing ability of most pos. pesticides. The Microtitration SOS Chromotest is rapid and efficient in providing evidence for decision-making related to cleanup of chem. spills and discharges where time is a crit. factor. This method maintains its high accuracy and sensitivity compared with conventionally used assays. The studies of pesticide genotoxicity using this test confirm the applicability, reliability, and sensitivity of the Microtitration SOS Chromotest as a simple, efficient, and rapid genotoxicity prescreening system as well as an excellent research tool for genotoxic mechanism studies. Methods for facilitating early elimination of potential P-gp substrates are useful for facilitating new drug discovery. A computational ensemble pharmacophore model has recently been used for the prediction of P-gp substrates with a promising accuracy of 63%. It is desirable to extend the prediction range beyond compds. covered by the known pharmacophore models. For such a purpose, a machine learning method, support vector machine (SVM), was explored for the prediction of P-gp substrates. A set of 201 chem. compds., including 116 substrates and 85 nonsubstrates of P-gp, was used to train and test a SVM classification system. This SVM system gave a prediction accuracy of at least 81.2% for P-gp substrates based on two different evaluation methods, which is substantially improved against that obtained from the multiple-pharmacophore model. The prediction accuracy for nonsubstrates of P-gp is 79.2% using 5-fold cross-validation. These accuracies are slightly better than those obtained from other statistical classification methods, including k-nearest neighbor (k-NN), probabilistic neural networks (PNN), and C4.5 decision tree, that use the same sets of data and mol. descriptors. The study indicates the potential of SVM in facilitating the prediction of P-gp substrates. [on SciFinder (R)] 0095-2338 P/ glycoprotein/ substrate/ drug/ design/ support/ vector/ machine

1405. Yakushko, V. E. and Zlatev, Z. D. (1975). Toxicity of Certain Acaricides and Changes in the Activity of Hepatic Microsomal Aminopyridine Demethylase During Combined and Separate Application. *Gig. Tr. Prof. Zabol.* 9: 55-57.
Chem Codes: Chemical of Concern: PSM Rejection Code: NON-ENGLISH.

ABSTRACT: PESTAB. The acute oral toxicity of binary mixtures of kelthane, milbex, and acrex with phthalophos, phosalone, dimethoate, and anthio, respectively, and the effect of milex, phosalone, and their combination on the hepatic microsomal aminopyridine demethylase activity were studied in albino mice and rats. The organochlorine and organophosphorus preparations were mixed at 2:1 ratio. While mixtures of kelthane and acrex with phthalophos and dimethoate, respectively, showed summation effect, judged from the LD50 value, all other combinations showed antagonistic effect. Phosalone, administered in 1/5 of LD50 dose for 3 consecutive days, increased the hepatic microsomal aminopyridine demethylase activity by a factor of 2 against the control, and milbex caused an increase by 3.8 times. The mixture of these two pesticides increased the enzyme activity by 7.4 times.

Citations: Yin, C; Water Res 2002, 36, 2975 This study was conducted to det. the relationships between 1381 chem. and structural parameters of 43 organophosphorus pesticides (OPs) and their toxicity to fish, C. carpio, using ChemOffice 8.03 and Dragon 2.1. By multivariate linear regression and intervariable regression analyses, various equations have been derived to calc. the lethal toxicity value, LC50, for 43 OPs found in fish with different levels of toxicity. Results show that for all selected OPs, esp. those of low toxic OPs (LC50 <2.5 mM), the equation, LC50 = 56.259 - 13.071 lg Kow + 17.510 MATS8P - 17.455 Mor24u - 0.085 MW + 1.706 (lg Kow)2 + 2.306 (Mor14e)2 + 6.849 Mor20m (n = 43, F = 36.815, r = 0.942, r2adj = 0.862 , SE = 2.899, $p < 10^{-6}$), could account for 86.2% of the variability of the toxic effect. The steric and electronic characteristics and the hydrophobicity of OPs, in particular, are among the most important parameters detg. the toxicity of OPs to fish. For the OPs with high toxicity, different structural parameters were introduced into the following 2 equations: LC50 = 3.795 - 1.195 (H1p)2 - 0.037 U - 2.225 MATS3v - 19.593 Tcon (n = 16, F = 56.820, r = 0.977, r2adj = 0.937, SE = 0.143, $p < 10^{-6}$), where LC50 is <2.5 mM, and LC50 = 0.341 - 0.561 (HOMA)2 + 0.231 HOMA (n = 3, r2adj = 1), where LC50 is <0.3 mM. These results suggest that chem. and structural parameters could be useful in modeling chem. reactivity within homologous series of OP compds. and elucidating possible mechanisms assocd. with different levels of toxicity to fish. 1407. Yan-Ming, Liu, Xiu-Ping, Yuan, and Qi-Ya, Zhang (2006). Spatial distribution and morphologic diversity of virioplankton in Lake Donghu, China. *Acta Oecologica* 29: 328-334.
Chem Codes: Chemical of Concern: PSM Rejection Code: VIRUS, BACTERIA, SURVEY.

The spatial distribution and morphological diversity of virioplankton were determined in Lake Donghu which contains three trophic regions: hypertrophic, eutrophic and mesotrophic region. Virioplankton abundance measured by transmission electron microscope (TEM) ranged from 7.7 x 108 to 3.0 x 109 ml-1, being among the highest observed in any natural aquatic system examined so far. The spatial distribution of virioplankton was correlated significantly with chlorophyll a concentration ($r = 0.847$; $P < 0.01$) at the sampling sites in Lake Donghu. 76 morphotypes were observed. Most morphotypes have tails, belonging to Siphoviridae, Myoviridae and Podoviridae. The majority of tailed phages in the lake were Myoviridae. Morphotypes which were rarely reported, such as prolate-headed virus-like particles, lemon-shaped virus-like particle, and viruses resembling Tectiviridae and Corticoviridae were all observed in the lake. It is concluded that the high viral abundance might be associated with high density of phytoplankton including algae and cyanobacteria. There was high viral diversity in this eutrophic shallow lake. In addition, cyanophage represented an important fraction of the virioplankton community in Lake Donghu. 1408. YANG, Hong-jun, SHEN, Zhe-min, ZHU, Song-he, and WANG, Wen-hua (2007). Vertical and temporal distribution of nitrogen and phosphorus and relationship with their influencing factors in aquatic-terrestrial ecotone: a case study in Taihu Lake, China. *Journal of Environmental Sciences* 19: 689-695.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE, BACTERIA.

Vertical and temporal distributions of N and P in soil solution in aquatic-terrestrial ecotone (ATE) of Taihu Lake were investigated, and the relations among N, P, ORP (oxidation reduction potential), TOC, root system biomass and microorganism were studied. As a whole, significant declines in TN, NO3--N, DON (dissolved organic nitrogen) and TP concentration in soil solution have occurred with increase of the depth, and reached their minima at 60 cm depth, except for NH4+-N, which increased with depth. The concentration of TP increased gradually from spring to winter in the topsoil, the maximum 0.08 mg/L presented in the winter while the minimum 0.03 mg/L in spring. In the deeper layer, the concentration value of TP fluctuated little. As for the NO3--N, its seasonal variation was significant at 20 cm depth, its concentration increased gradually from spring to autumn, and decreased markedly in winter. Vertical and temporal distribution of DON is contrary to that of NO3--N. The results also show that the variation of N and P in the percolate between adjacent layers is obviously different. The vertical variation of TN, TP, NO3--N, NH4+-N and DON is significant, of which the variation coefficient of NO3--N along the depth reaches 100.23%, the highest; while the variation coefficient of DON is 41.14%, the smallest. The results of correlation analysis show that the concentration of nitrogen and phosphorus correlate significantly with TOC, ORP, root biomass and counts of nitrifying bacteria. Most nutrients altered much from 20 to 40 cm along the depth. However, DON changed more between 60 and 80 cm. Results show that soil of 0-60 cm depth is active rhizoplane, with strong capability to remove the nitrogen and phosphorus in ATE. It may suggest that there exists the optimum ecological efficiency in the depth of above 60 cm in reed wetland. This will be very significant for ecological restoration and reestablishment. aquatic-terrestrial ecotone (ATE)/ soil percolate/ vertical and temporal distribution/ coefficient of variation/ ecological efficiency http://www.sciencedirect.com/science/article/B8CX4-4NXH6S2-B/2/1fba8d8226413628a89dbcff5fb3c072

1410. Yap, Nida L. and Rao, Venigalla Basaveswara (1996). Novel Mutants in the 5' Upstream Region of the Portal Protein Gene20Overcome a gp40-dependent Prohead Assembly Block in Bacteriophage T4. *Journal of Molecular Biology* 263: 539-550.
Chem Codes: Chemical of Concern: PSM Rejection Code: VIRUS.

The exact mechanism by which the double-stranded (ds) DNA bacteriophages incorporate the portal protein at a unique vertex of the icosahedral capsid is unknown. In phage T4, there is evidence that this vertex, constituted by 12 subunits of gp20, acts as an initiator for the assembly of the major capsid protein and the scaffolding proteins into a prolate icosahedron of precise dimensions. Assembly of the T4 initiator vertex occurs on the membrane and is facilitated by the non-structural protein gp40. gp40 apparently acts as a catalyst for the gp20 assembly and a direct interaction between gp20 and gp40 has been proposed based on the genetic evidence that second site suppressors of g40mutants map in g20. But, surprisingly, we found that these40bypass mutants arose not by alterations in the g20structural gene, but by alterations in the upstream non-coding region. At least six independent bypass mutants were isolated with all except one having mutations in the non-coding region. The only exception that had a mutation in the coding region was a silent mutation, since it did not alter the amino acid sequence of gp20. The bypass mutants produced a three- to fivefold overexpression of gp20. That the gp20 overexpression is directly responsible for40bypass was shown by a number of approaches. The overexpression was apparently due to a secondary structural change in the g20transcript resulting in an enhanced translational initiation of g20message. The data suggest that the regulation of portal protein gene expression is an important regulator of prohead assembly in bacteriophage T4. bacteriophage T4; portal protein; bypass mutants; chaperone; prohead assembly

The environmental equil. distributions and levels of persistency of 20 selected organophosphorus

insecticides have been detd. using Mackay's Level II Fugacity Model. The model comprised air, water, biota, soil, suspended solids, and sediment compartments. Available physicochem. and kinetic data for the insecticides have been compiled. Results suggest that some of the insecticides have tendencies to occur at high concns. in biota and may be environmentally persistent. Of these, 19,146 were surveillance samples, collected with no evidence of illegal pesticide residues. No pesticide residues were found in 60% of the 8879 domestic surveillance samples and 64% of the 10,267 import surveillance samples. In an aquaculture survey, 172 samples of shell- and finfish were analyzed for some environmentally persistent pesticides. Low levels of chlorinated pesticide residues, none of which exceeded EPA tolerances or FDA action levels, were found in a no. of samples. A survey of pasteurized whole milk from U.S. metropolitan areas found that residues of chlorinated pesticides were present in about 53% of the 330 samples. In a survey of processed foods, including baby foods and nuts, 3502 samples were analyzed for various pesticides. No residues were found that were over tolerance or for which there was no tolerance. In the Total Diet Study, which measures pesticide residues in foods, as consumed. 936 food items representing the diets of U.S. consumers were analyzed. Of the >200 chems. that can be detd. by the anal. methods used, 51 were found in the foods analyzed. As in previous years, the levels of estd. dietary intakes of the pesticides found were generally well below established stds. The results from regulatory monitoring, incidence/level monitoring, and the Total Diet Study for 1990 agree with findings from earlier years and corroborate the continuing safety of the U.S. food supply relative to pesticide residues. The 1991 report explains the 3 approaches FDA uses to carry out its pesticide program, gives results for Fiscal Year (FY) 1991, and summarizes the findings for the 5 yr of annual report publication. Under its monitoring focused on enforcing tolerances set by the Environmental Protection Agency, FDA analyzed a total of 19,082 samples of domestically produced food from all 50 states and Puerto Rico and imported food from 102 countries. Of these, 18,214 were surveillance samples, collected when there was no evidence that a shipment might contain illegal pesticide residues. No pesticide residues were found in 64% of the 8281 domestic surveillance samples and 69% of the 9933 import surveillance samples. Under incidence/level monitoring, 3 projects were carried out in FY91. In an aquaculture survey, 188 samples of shell- and finfish were analyzed for some environmentally persistent pesticides. Low levels of chlorinated pesticide residues, none of which exceeded EPA tolerances or FDA action levels, were found in a no. of the samples. A survey of pasteurized whole milk from U.S. metropolitan areas found that residues of chlorinated pesticides were present in about 49% of the 806 samples. In surveys covering a variety of foods, including baby foods; bananas and citrus fruits; dried beans, dried fruits, and rice; foods with postharvest uses and/or food additive tolerances; and processed foods, a total of 5565 analyses were performed for

selected pesticide residues. No residues were found that were over tolerance or for which there was no tolerance. In the Total Diet Study, which measures pesticide residues in foods as consumed, 936 food items representing the diets of U.S. consumers were analyzed. Of the >200 chems. that can be detd. by the anal. methods used, 51 were found in the foods analyzed. As in previous years, the levels of estd. dietary intakes of the pesticides found were generally well below established stds. A summary of FDA's pesticide residue findings for FY87-FY91 shows consistently low nos. of violative samples, and thus confirms the safety of the food supply relative to pesticide residues. The results of monitoring infant foods and adult foods that may be eaten by infants/children under these 3 approaches are presented. Under regulatory monitoring, which is performed to enforce tolerances set by the U.S. Environmental Protection Agency (EPA), during fiscal years 1985-1991, over 10,000 such domestic and imported food samples were collected and analyzed, and under the Total Diet Study, in which pesticide residue intakes are estd. in foods prepd. for consumption, the food items in 27 market baskets were analyzed. Under incidence/level monitoring, which is complementary to regulatory monitoring, over 4000 analyses were performed on infant foods and adult foods eaten by children. Fewer than 50 of the 10,000 regulatory samples had violative residues; nearly all of those were residues for which there was no tolerance set for the particular commodity/pesticide combination. Under incidence/level monitoring and the Total Diet Study, the levels of pesticide residues found in infant foods and adult foods eaten by children were well below tolerances set by EPA. [on

Abstract: Two genotypes of Lotus tenuis Waldst and Kit. ex Willd. PI 204882, a diploid (2n = 2x = 12), were identified as producing 2n pollen (maximum =6%). The objectives of this research were: (1) to determine the mechanism(s) of 2n pollen formation in the L tenuis genotypes and (2) to morphologically describe n and 2n pollen using light and scanning electron microscopy. Meiotic studies revealed that 2n pollen resulted from tripolar spindles during anaphase II of microsporogenesis. The 2n pollen germinated well, although abnormal pollen tubes were observed. The genetic constitution of 2n pollen resulting from tripolar spindles is equivalent to first division restitution (FIR) of meiosis. Fresh and air-dried pollen samples exhibited differences in size and shape under light and scanning electron microscopy. The size of diphloid (2/n) pollen was larger than that of haploid (In) pollen. Normal haploid (1n) pollen was globose-prolate in shape, while diploid (2n) pollen was tetrahedral in shape.

1418. Yonova, I. and Zhecheva, G. (Residues of Sevin, Neguvon, and Imidan in the Meat of Pigs Treated for Ectoparasites. *Vet. Med. Nauki 11(5): 28-34* 1974..
Chem Codes: Chemical of Concern: PSM Rejection Code: NON-ENGLISH.

ABSTRACT: PESTAB. A study was made of 56 one-year-old pigs which had been treated topically for ectoparsite control with sevin (carbaryl), neguvon (trichlorfon), and imidan (phosmet). The animals were killed in succession up to the 50th day after treatment. Pesticide residues were extracted from samples of kidney fat and meat from the thigh and shoulder as well as liver tissue by a modification of the method of Brewerton and Langlois. Subsequent estimations were carried out by McRae and McKinley's method using thin-layer chromatography. The results of the study indicated that the pesticides penetrated through the skin for 2 to 5 days. They accumulated predominantly in the s.c. fat, sevin at 10 ppm, neguvon at 12 ppm, and imidan at 10 ppm. Also they accumulated partly in the meat: sevin at 6 ppm, neguvon at 7 ppm, and imidan at 8 ppm. The metabolism of the pesticides was also followed and several metabolites were identified.

(Protecting Effect of a Green Tea Percolate and Its Main Constituents Against Gamma Ray-Induced Scission of Dna. *Biosci biotechnol biochem. 1996, jan; 60(1):117-9. [Bioscience, biotechnology, and biochemistry]: Biosci Biotechnol Biochem*.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

ABSTRACT: Gamma ray-induced scission of puC18 plasmid DNA prepared from E. coli was examined in the presence of a green tea percolate and its main constituents, L-ascorbic acid (used as the sodium salt) and (-)-epigallocatechin gallate. Each of these showed a protecting effect against DNA scission. The relationship between the protecting effect against DNA scission and the scavenging effect of the hydroxyl radical was examined, and is discussed from the viewpoint of interaction with DNA.

1420. Yoshioka, H., Kurosaki, H., Yoshinaga, K., Saito, K., and Yoshioka, H. (1997). Beta Ray-Induced Scission of Dna in Tritiated Water and Protection by a Green Tea Percolate and (-)-Epigallocatechin Gallate. *Bioscience biotechnology and biochemistry* 61: 1560-1563.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. The beta-ray induced scission of puC18 plasmid DNA from E. coli in tritiated water was examined in the presence or absence of a green tea percolate (TP) and the main constituent, (-)-epigallocatechin gallate (EGCg). An analysis of the ratio of the original closed-circular to the open-circular form of DNA, which was formed by the strand scission of DNA, revealed that TP and EGCg showed a protective effect on DNA scission depending on their concentrations. A new technique, named solid state spin trapping, was applied to examine this scavenging ability toward the hydroxyl (OH) radical generated in tritiated water. The result was kinetically analyzed to reveal that TP and EGCg showed the scavenging effect, suggesting that the protective effect on DNA scission was attributable to the scavenging effect on the OH radical.

1423. Yousef, Y. A., Wanielista, M. P., Harper, H. H., Pearce, D. B., and Tolbert, R. D. (Best Management Practices: Removal of Highway Contaminants by Roadside Swales. *Govt reports announcements & index (gra&i), issue 03, 1986*.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: TD3: A research project to investigate the best management practices for highway runoff is being conducted. One phase of the project is to study the removal of highway contaminants by roadside swales. Their hydraulic efficiencies are based on their ability to infiltrate and percolate stormwater. Field experiments were designed to study pollutant concentrations and mass balances during flow through swales under controlled environments. From the results obtained, it appears that ionic species of metals, nitrogen and phosphorus species may be retained on the swale site by sorption, precipitation, co-precipitation and biological uptake processes. These processes can reduce pollutant concentrations in highway runoff flowing over swales. Final rept. on Phase 1, Jan 82-Mar 85, Sponsored by Federal Highway Administration, Tallahassee, FL. Florida Div., Florida State Dept. of Transportation, Gainesville. Bureau of Materials and Research, and Florida State Dept. of Transportation, Tallahassee. Bureau of Envi

Abstract: Heavy metals (Cu, Pb, Zn) in highway runoff entering detention ponds are removed by physical, chemical, and biological processes, and concentrate in the bottom sediments. Soluble metal fractions percolate into the bottom sediments and produce a potential for contamination of

groundwater. Therefore, a two-year research project was supported by Florida Department of Transportation and US Federal Highway Administration to study the fate and migration of these metals in bottom sediments of six wet detention ponds, located in Florida. Sorption, molecular dispersion, and pilot studies were conducted in the laboratory to investigate metal transport through the sediment cores collected from these ponds. The results showed that the flow of metals through the bottom sediments is a very slow process. Most of these metals are retained in the top 15-20 cm of sediments and saturation of this layer may take years. Removal of accumulated bottom sediments at time intervals averaging 25 years would be sufficient to minimize the potential contamination of groundwater. Also existing models were modified to simulate metal transport through the bottom sediments in wet detention ponds.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. The extensive international use of organophosphorus compounds (OP) results in numerous acute intoxications each year. OPs inhibit acetylcholinesterase, the enzyme responsible for breaking down the neurotransmitter acetylcholine. The World Health Organization recognizes cholinesterase (ChE) biomonitoring as a preventive measure against OP overexposure. The aim of this study was to determine if dermal OP contamination could interfere with current field ChE biomonitoring assays, which use a fingerstick blood sample. in this study we also sought to determine if high levels of a plasma enzyme, A-esterase, could protect ChE from inhibition by hydrolyzing environmentally generated oxons potentially present in a fingerstick sample. A heparinized venous blood sample was collected from a volunteer. Erythrocyte acetylcholinesterase (AChE) and plasma butyrylcholinesterase (PChE) activities were measured using a field-based colorimetric cholinesterase kit. ChE dose-response curves w

1428. Zabka, Jan, Dolejsek, Zdenek, Hrusak, Jan, and Herman, Zdenek (1999). A crossed beam scattering study of reactions in the system acetylene cation-acetylene: formation of C2HD+[middle dot]in C2D2+[middle dot] + C2H2 and formation of C4H3+ and C4H2+[middle dot] in C2H2+[middle dot] + C2H2 collisions. *International Journal of Mass Spectrometry* 185-187: 195-205.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Dynamics of chemical reactions in the system acetylene cation-acetylene was investigated in crossed beam scattering experiments. Relative cross sections of formation of various products at T = 2.5 eV were C4X3+ : C4X2+[middle dot]: C2X2+[middle dot] = 1.0:0.55:0.17 (X = H, D). C2X2+[middle dot] (C2HD+[middle dot] from C2D2+[middle dot] + C2H2 collisions) traces the decomposition of an intermediate complex C4X4+[middle dot] backward to reform the reactants; the mean lifetime of the intermediate is longer than about 5 ps and its geometry in the critical configuration close to linear. The products C4H3+ and C4H2+[middle dot] are formed in exoergic reactions by the decomposition of a long-lived intermediate C4H4+[middle dot] of prolate geometry in its critical configuration. About 15% of the energy available at T = 1.5 eV in the latter two processes may be expected to be deposited as rotational energy of the product ion. Ion-molecule reactions/ Collisional dynamics/ Beam scattering/ Intermediate complex formation

<u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: ABSTRACT.

ABSTRACT: PESTAB. Peach trees were sprayed 3-4 times with phosalone (30%), carbaryl, phthalophos (phosmet), and trichlorfon to control Grapholitha molesta Busch. The application rate was 3 liters of broth per tree. The residues in peaches were determined by thin-layer chromatography. Phosalone, phthalophos and trichlorfon residues were not detectable in the fruit 10 days after spraying, at which time the carbaryl residue level was 1.2 mg/kg. Carbaryl residues were found for over 30 days; the residue level was 0.3 mg/kg on the 24th day. The findings indicate that carbaryl is not recommended for use on peach trees because of its slow degradation.

Organophosphate (OP) pesticides were recommended during the dormant season to control overwintering insects such as peach twig borer, San Jose scale, European red mite, and brown mite in California almond and stone fruit orchards. However, since 1990, dormant OP use had fallen under increased scrutiny due to surface water contamination concerns. Studies have shown pos. correlation between OP use and residue load in surface water. The purpose of this study is to assess the trends and regional patterns of OP use in almond orchards, and to identify factors that may have influenced those trends, including weather, pest pressure, and use of alternatives to OP such as pyrethroid, dormant oils, and Bacillus thuringiensis (Bt) for the assessment of the impacts to surface water quality. Pesticide use data from the California Department of Pesticide Regulation were analyzed. Regression analyses were used to assess trends from 1992 to 2000, and a geog. information system (GIS) was used to visualize the spatial variation in pesticide use. Results from this study indicated that, statewide, dormant OP use decreased while the use of some alternatives, such as dormant pyrethroid, no dormant insecticides, and in-season pyrethroid, oil alone, and Bt, increased in the last 9 years. The significant decreasing trend of OP use was obsd. for the measures of kilogram per ha crop planted, percentage of total planted ha treated, and nos. of growers who applied dormant OP. The redn. of dormant OP use appeared in all major almond-growing counties. Correlation analyses revealed that more rain was assocd. with less dormant OP use. A higher percent of almond damage, or rejects, was related to higher OP use in the following dormant season and in-season periods. However, the effects of weather and percent of nut rejects can only explain small portion of the variations in dormant OP use. Therefore, in addn. to weather and pest pressures, economic pressures and various outreach and extension programs may also have played a role in encouraging farmers to reduce their use of dormant OP. The rf source can operate in He at <1 W of load power at 165 kHz. It can also be sustained in Ar, N2, air, and CO2 at a load power of <15 W. In most cases studied, the protonated mol., MH+, is obsd. with little or no fragmentation even under the relatively high current conditions of the discharge. However, using increasingly higher acceleration voltages between the skimmers in the differentially pumped region between atm. pressure and high vacuum, one can induce fragmentation via collision-induced dissocn. This can be assisted in these expts. via the use of a heavy buffer gas. The detection limits achieved for rf/API plasma detection are typically in the low femtomole region for small org. mols. including neurotransmitters, PTH-amino acids, steroids, drugs, pesticides, and explosives. The detection can be performed with quantitation over at least 4 orders of magnitude. 1436. Zhu, X. Y. (2004). Pollen and Seed Morphology of Gueldenstaedtia and Tibetia (Leguminosae) - With a Special Reference to the Taxonomic Significance. *Nordic Journal of Botany, 23 (3) pp. 373-384, 2004.*
Chem Codes: Chemical of Concern: PSM Rejection Code: SURVEY.

ISSN: 0107-055X
Abstract: The pollen morphology of Gueldenstaedtia gansuensis, G. gracilis, G. henryi, G. monophylla, G. mutiflora, G. stenophylla, and G. verna and Tibetia liangshanensis, T. tongolensis, T. yadongensis, T. coelestis, and T. yunnanensis are reported for the first time. The seed morphology of G. gracilis, G. maritima, G. monophylla, G. mutiflora, G. taihangensis, and G. verna and T. coelestis, T. himalaica, T. yunnanensis, and T. yadongensis are firstly described here. In pollen morphology, the differences of pollen grains of Gueldenstaedtia and Tibetia are as follows: Gueldenstaedtia with pollen grains 3-colporate, psilate, and shapes spheroidal, sometimes subprolate, prolate or oblong; and Tibetia with pollen grains 3- and 4-colporate, perforate, shapes spheroidal, sometimes subprolate or prolate. These results, combined with the data of the basic chromosome number x=7 of Gueldenstaedtia and x=8 of Tibetia, support that the two genera should be recognized as two distinct genera, which are consistent with their morphological characters: Gueldenstaedtia with 2 upper lobes of calyx free, stipules free, adnate to petiole, and Tibetia with 2 upper lobes of calyx connate, stipules connate and opposite to leaves. In Tibetia, two types of pollen grains, 3- and 4-colporate pollen grains, are found. Regarding seed

morphology: Gueldenstaedtia has circular depression, irregular circular depression or irregular circular reticulation on the surface; Tibetia has smooth surface. The differences in seed morphology of the two genera also support that they should be kept separate. The pollen morphology supports that G. gansuensis, G. gracilis, G. multiflora, G. stenophylla, and G. verna should be reduced into one species consistent with their morphological characteristics. The pollen grains of G. henryi are different from those of the other species in having wide colpi.

Thus, 1-(3-chloro-2-pyridinyl)-3-trifluoromethyl-1H-pyrazole-5-carboxylic acid (prepn. given) was stirred with (COCl)2 and cat. DMF in CH2Cl2 to give crude acid chloride, which was refluxed 3 h with 8-methyl-2H-3,1-benzoxazine-2,4(1H)-dione (prepn. given) and pyridine in MeCN to give 2-[1-(3-chloro-2-pyridinyl)-3-trifluoromethyl-1H-pyrazol-5-yl]-8-methyl-4H-3,1-benzoxazin-4-one. The latter was refluxed 1.5 h with Me2CHNH2 to give 1-

(3-chloro-2-pyridinyl)-N-[2-methyl-6-[[(1-methylethyl)amino]carbonyl]phenyl]-3-trifluoromethyl-1H-pyrazole-5-carboxamide. This was stirred overnight with DBU in MeCN to give N-(3-chloro-2-pyridinyl)-N-[2-methyl-6-[[(1-methylethyl)amino]carbonyl]phenyl]-5-trifluoromethyl-1H-pyrazole-3-carboxamide. The latter at 250 ppm on radishes preinfested with Plutella xylostella gave ?10% feeding damage. [on SciFinder (R)] C07D401-12. Chem Codes: Chemical of Concern: PSM Rejection Code: NON-ENGLISH.

ABSTRACT: PESTAB. The contact toxicity of the insecticides chlorofos (trichlorfon), dilor, and phthalofos (phosmet) and the fungicide polycarbazine to Colorado potato beetle and its predator Podisus maculiventris Say was studied. Chlorofos was found to be more toxic to the predator than to Colorado beetle (LC50. were 0.28 and 12.6 mug/g, respectively). Dilor toxicity to Podisus was low (195 mug/g, compared with 7.08 for Colorado beetle). The LC50 of phthalofos for Podisus and Colorado beetle were 4.61 and 3.0 mug/g, respectively. Polycarbazine was extremely toxic to Podisus larvae. The indexes of selectivity of chlorofos, dilor, and phthalofos were 0.02, 22.0, and 1.20, respectively.

Chem Codes: Chemical of Concern: PSM Rejection Code: NON-ENGLISH.

ABSTRACT: PESTAB. To evaluate the role of microsomal enzymes in detoxication of pesticides, the synergism between piperonyl butoxide (PPB) and the pesticides Neopinamine (tetramethrin), phthalophos (phosmet) and Orthene (acephate) was studied in sensitive (S) and resistant (R) house flies strains. Flies were treated with pure insecticide at various concentrations or with insecticide in mixture with PPB (1:5 ratio); the synergistic activity was estimated by the coefficient of combined effect (CCE). The CCE values for flies resistant to Neopinamine and Orthene were 12.0 and 4.0, respectively (compared with 3.6 and 2.2 for sensitive strains). There was a direct relationship between the degree of resistance to phthalophos and the synergistic effect. These findings indicate that esterase hydrolysis of thioester bond is the major pathway of detoxication in mildly resistant flies, while in highly resistant flies, hydroxylases were induced by phthalophos and inhibited by PPB.

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. The degradative kinetics of pesticides on plant surface are characterized by an initial rapid degradation which follows a first-order kinetics, then transferred to a more slower degradative rate. The degradative process mainly consists of photodegradation, evaporation, rainfall elution and growth dilution. The influencing parameters of

these processes were investigated by using the tea plant as a case study. The predictive model of the initial concentration, photodegradation rate constant, evaporation rate constant, rainfall elution rate, growth dilution rate and the total degradation rate was discussed and verified in four locations situated in the range of 25ę-30ęN latitude, and acceptable results were obtained.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. The special agro-biological character and beverage purpose of the tea plant, Camellia sinesis, determine a strict selection of the pesticides used in tea production. Some guidelines including the efficiency, activity spectrum, toxicity, degradative rate on/in tea shoots, taint and extractive rate in the infusion are discussed. The major pests and diseases of the tea plant and the evolutional change of pesticides used in tea production in China are listed.

1444. Zor'eva, R. D. (Chromatographic Determination of Phosmet in Soil and Washings. *Khim. Sel'sk. Khoz. 15(8): 19-20 1977 (2 references).*
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: PESTAB. A thin-layer chromatographic method for the determination of phosmet in soil and in washings obtained from plants with acetone and from skin with ether or acetone is described. Following extraction with acetone and reextraction with chloroform, the chloroform extract is evaporated, and the dry residue is dissolved in ether and applied to a LS 5/40 silica gel plate, using a 1/2 mixture of acetone and hexane as the solvent system. After drying, the plate is sprayed with a water-acetone mixture of bromphenol blue and silver nitrate. Phosmet appears in the form of dark blue spots. Quantitative determination is possible by assessing the intensity and size of the spots. The sensitivity amounts to 1 mug; the recovery rate is about 90%.

Citations: 35) Anon; Principles and Practices of Method Validation 2000, 179 A method using simultaneous pulsed flame photometric (PFPD) and micro-electron capture detection (mECD) in gas chromatog. (GC) was developed and validated for the anal. of 23 organophosphorus (OP) and 17 organochlorine (OC) pesticides in animal fat. The method entailed the extn. of animal tissue (mixed with twice the sample wt. of sodium sulfate) with 7 mL Et acetate per 1 g tissue. After the blending step, the ext. was centrifuged and 3 mL cyclopentane was added to a 7 mL portion of the ext. A 2.5 mL portion was injected into a 2 cm ID * 22.5 cm Biobeads S-X3 gel permeation chromatog. column (4.5 mL/min flow rate of 70/30 Et acetate/cyclopentane). A 36 mL fraction (from 8 to 16 min) was collected, evapd., and solvent-exchanged to 1 mL final vol. in iso-octane. The GC/PFPD+mECD system used a single injector and column, but the flow was split after the chromatog. sepn. to the two detectors. The final ext. was injected (2 mL) into the GC/PFPD+mECD system for simultaneous anal. of the OP and OC analytes. The PFPD was used in the phosphorus-only mode to detect OPs and the mECD mainly detected halogenated pesticides but a few N-contg. OPs could be sensitively detected with it as well. Recoveries were 60-70% for the bulk majority of pesticides except for methamidophos, acephate, and omethoate which are more difficult in GC anal. due to their more polar nature. Fenthion and phorate also gave more variable recoveries, presumably due to their degrdn. to sulfones and sulfoxides. In fortification recovery expts. at several different concns. over multiple days, reproducibilities of 10-20% relative std. deviation were achieved, and limits of quantitation were typically 10-20 ng/g. 1447. Zygadlo, M. (1998). International Report: the Impact of Industrial Waste Landfill on Drinking Water in Poland. *Waste management & research* 16: 490-494.
<u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: FATE.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. This report presents the state of industrial waste landfills in Poland. It analyses the contamination of groundwater with industrial wastes at a site belonging to a metallurgical factory located in the Kielce province (central region of Poland). In landfill leachates, there exists a considerable amount of toxic substances like phenols, formaldehyde, cyanides, detergents and others which, due to improper bedding tightness, seriously threatens groundwater, including the drinking water intake for the City of Konskie (located 3 km from the landfill). Toxic substances are washed-out from wastes with rain water and, because of unfavourable geological structure, percolate into the Quaternary and then the Jurassic level. In order to prevent water intake contamination, it is necessary to keep the quantity of water extracted to a reduced level.
